Elmar P. Biernat

Electromagnetic Properties of Few-Body Systems Within a Point-Form Approach

Dissertation

zur Erlangung des Doktorgrades der Naturwissenschaften
an der Karl-Franzens-Universität Graz

Eingereicht am Institut für Physik

Betreuer:
Ao. Univ.-Prof. Mag. Dr. Wolfgang Schweiger

Graz, 2011

Präambel

Ich, Elmar P. Biernat, bestätige, dass es sich bei der hier vorgelegten Dissertation um eine Originalarbeit handelt, die von mir selbständig angefertigt und abgefasst wurde.

Chapter 1

Introduction

1.1 Motivation

With the discovery of the non-point-like nature of hadrons and nuclei from electron scattering experiments [Hof57, Hof63] the investigation of the structure of hadronic systems has become a vital field of research in modern nuclear and particle physics. According to quantum chromodynamics (QCD), which is accepted as the fundamental theory of the strong interaction, hadrons are bound states formed by strongly interacting quarks. The details of this mechanism are, however, not completely understood due to calculational difficulties that arise with a strongly-interacting quantum field theory in the low energy regime (see for example Ref. [AH03]). The nuclear force acting between nucleons is regarded as a residual force of the underlying strong interaction and is responsible for the binding of nucleons to form nuclei.

Ab initio calculations of hadron masses and the structure of hadrons require a non-perturbative solution of the QCD bound-state problem. This can be done by lattice as well as continuum methods, but only through enormous computational efforts. Therefore many effective models have been developed with the purpose providing a phenomenological description of hadronic properties. It is clear that such models, describing phenomena at length scales of nuclei (and smaller) and at energies and momenta used in electron-nuclei scattering experiments, should incorporate both, quantum theory and special relativity. A particular model that does not exhibit the difficulties of a strongly interacting quantum field theory at low energies and at the same time unifies quantum theory and special relativity is *relativistic quantum mechanics*. The foundation of such a model has been laid by Wigner [Wig39] and Bargmann [Bar54]. Contemporaneously, with his work about the *forms of relativistic dynamics* [Dir49], Dirac found 3 preferred ways of how to include interactions into a relativistic theory. He called them *instant*, *front* and *point form* according to the hypersurfaces in Minkowski space that are left invariant under the action of maximal sets of Poincaré transformations which are not affected by interactions (these are called *kinematic*). The point form, in particular, is characterized by the kinematic nature of Lorentz boosts and rotations.

The point form of dynamics has already been considered in the context of quantum field theory (see, e.g., Refs. [FHJ73, GRS74, BKSZ08, Kli08]).

How to put the idea of a point-form quantum field theory into practical use is currently under investigation using the analytically solvable Schwinger model [Sch51, Sch53]. The long-term goal is then to end up with a point-form formulation of QCD (for a recent review, cf. Ref. [BKS11b]).

The point form can also be applied to quantum systems with a finite number of degrees of freedom which generates a *point-form relativistic quantum mechanics* (PFRQM). A particularly simple Poincaré invariant prescription of how to set up an interacting quantum mechanical model is the *Bakamjian-Thomas construction* [BT53]. What one loses, however, in a Bakamjian-Thomas framework (for more than 2 particles) is cluster separability [Sok79, CP82] (for a detailed discussion of this problem see Ref. [KP91]). For the three-particle case a solution to the cluster problem (formulated in terms of S-operators) has been given by Coester [Coe65]. A general solution for an arbitrary number of particles has been proposed by Sokolov by introducing unitary operators, so-called *packing operators*, that restore cluster separability [Sok79]. This solution is, however, rather formal and cumbersome for practical purposes.

PFRQM has already been quite successfully applied to various problems of relativistic few-body physics, such as the calculation of masses [GPVW98, GKP$^+$05, MPS08], strong decays of hadrons [MPW05, MPS07, SMP07], strong form factors [MCP09], axial charges [CPW10a, CPW10b] and for a classification of baryons [MPS08].

In the present work we concentrate on the study of electromagnetic properties of few-body systems. The phenomenological quantities associated with the electromagnetically probed structure of a hadronic bound system are the *electromagnetic form factors*. They encode, in a relativistic invariant manner, all effects coming from the underlying QCD that influence the electromagnetic vertex of the bound state.

Finding a microscopic description of the form factors amounts to finding an expression for the electromagnetic bound-state current in terms of the electromagnetic constituent currents and bound-state wave function. Due to the requirement of covariance the current cannot be the simple sum of constituent currents. This was first realized by Siegert [Sie37]. Further constraints on the bound-state current come from the requirements of current conservation and cluster separability [Lev95].

There have been various attempts within relativistic few-body physics to calculate form factors. For instance, the form factors of the simplest hadronic systems like the π meson, the ρ meson and the deuteron have been investigated extensively in different approaches, most of them using light-front dynamics; see, for example, Refs. [CPCK88, BH92, CPSS95, CK99, AKP01, BCJ02, GG02, Jau03, CJ04, dMFPS06, BdT08, CKMB09]. Also PFRQM has already been used to analyze the electromagnetic structure of such simple hadronic two-body systems; see, for example, Refs. [Kli98a, AK98, AKP01, WBK$^+$01, B$^+$02, MBC$^+$06, MBC$^+$07]. In these approaches the point-form spectator model is used to define an electromagnetic current operator which already satisfies all the necessary requirements in order to be compatible with a particular interaction model [Lev95].

In the present work however we follow a different strategy. Rather than making an ansatz for the most general current on which the necessary constraints are imposed, we derive a microscopic bound-state current that exhibits the required properties. Our approach is based on a relativistic multi-channel framework proposed by Klink [Kli03a], using field theoretical vertex interactions that are implemented in the Bakamjian-Thomas construction. This multi-channel formalism has already been applied successfully to different relativistic few-body problems such asthe calculation of vector-meson masses and partial decay widths within the chiral constituent model [Kra01, KSK03, Kle10, KS10], the study of the hydrogen atom and positronium [Lec03] and for the derivation of a mass operator for pion-nucleon and nucleon-nucleon scattering using chiral perturbation theory [GVK07]. This formalism, adapted to electron-bound-state scattering, makes it possible to calculate electromagnetic bound-state currents. It was first proposed in Ref. [Fuc07] for the case of a pseudoscalar quark-antiquark bound state in which the quarks were treated, for simplicity, as spinless particles. Despite this simplification, the form factor results were already quite promising. In particular, they showed perfect numerical agreement with the results of the standard front-form approach by [CCP88]. The deeper reason for this equivalence was, however, not yet evident. The present work, where the constituents' spins are fully taken into account, attempts to give an explanation to this question. Moreover, by investigating spin-0 and spin-1 form factors and addressing the cluster problem we will find quite remarkable similarities with the covariant light-front approach of Refs. [KS94, CDKM98]. The present work also contains part of a benchmark calculation of the deuteron form factors, whose aim is to define more accurately the meaning of 'relativistic effects' in different approaches of few-body physics. As a common starting point, we propose a simple model for the nucleon-nucleon interaction in the spirit of the Walecka model [Wal74].

The same coupled-channel formalism has also been applied very recently to calculate electromagnetic and weak form factors of heavy-light systems [GRS11, GRS10]. Therein, a simple analytical expression for the Isgur-Wise function [IW89, IW90] has been found in the heavy-quark limit.

In this thesis we restrict ourselves to instantaneous interactions between the constituents that form the bound state. The formalism offers, however, the possibility to include additional channels with dynamical particle-exchange interactions between the constituents. Such an extension is under investigation and will not be part of this thesis.

To sum up, the great advantage of our point-form approach is manifest Lorentz covariance which will be used to derive currents and form factors for spin-0 and spin-1 bound states of two spin-1/2 particles. Due to the Bakamjian-Thomas framework we expect, however, difficulties associated with cluster separability. How such difficulties manifest themselves and how they can be circumvented is the second important issue of this thesis.

1.2 Synopsis

Chap. 2 is an introduction to relativistic quantum mechanics. It provides the theoretical background on which the present work is based. We point out the relevance of the universal covering group of the Poincaré group for a relativistic quantum theory and derive the Casimir operators of the Poincaré group. With the one-particle irreducible representations we construct multi-particle representations, one of them being the velocity-state representation which is most convenient for our purposes.

Chap. 3 is devoted to interactions in a Poincaré invariant quantum theory.

This brings up the notion of Dirac's forms of relativistic dynamics, where we focus in particular on the point form. A Poincaré invariant prescription for how to introduce interactions into a free theory is the Bakamjian-Thomas construction, which is then used to formulate the bound-state problem for a mass operator. In this context we address the non-trivial problem of cluster separability. The definition of appropriate electromagnetic vertex interactions in terms of field-theoretical interaction densities concludes this chapter.

Subsequently, in Chap. 4, we set up a relativistic coupled-channel problem which describes center-of-mass electron-bound-state scattering in the one-photon-exchange approximation. From the associated optical potential we extract the electromagnetic bound-state current in terms of constituent currents and bound-state wave functions. Properties of the current such as hermiticity, continuity and covariance are discussed for the particular cases of spin-0 and spin-1 bound states.

The subject of Chap. 5 is the extraction of the electromagnetic form factors from the expression for the bound-state current, which requires a careful analysis of its Lorentz structure. In this context it will be necessary to come back to the problem of cluster separability. By comparing our expressions for the current and the form factors with those of light-front dynamics notable similarities are found.

In Chap. 6 we introduce specific models for bound states. For mesons, like the π and ρ meson, we model confinement between the quarks by a simple harmonic-oscillator potential. For the deuteron we propose a meson-exchange nucleon-nucleon interaction inspired by the Walecka model.

The numerical results for our form factors of the pion, the ρ meson and the deuteron are then presented and discussed in Chap. 7.

Chap. 8 finally summarizes the thesis and gives a short outlook to further investigations.

The appendices contain important definitions and conventions to be used throughout the work together with basic relations, longer derivations and involved calculations. App. A gives the Minkowski space notations and a matrix representation of the Poincaré group in Minkowski space. App. B gives the representations to be used for the Dirac spinors and the polarization vectors together with their most basic properties and relations. App. C contains some useful relations associated with the SL$(2,\mathbb{C})$ and the Clebsch-Gordan coefficients. In App. D we give the rather lengthy calculations and derivations of the currents obtained in Chaps. 3 and 4. In App. E we detail the derivation of the microscopic bound state current from the optical potential. App. F contains a detailed analysis of the extraction of the form factors described in Chap. 5. Finally, App. G gives the derivation of the meson-exchange potentials in the static approximation used in Chap. 6.

Chapter 2

Relativistic Quantum Mechanics

In this chapter we present and briefly discuss the fundamental principles and ideas on which the present work is built. It provides the basis for the following chapters. We will proceed roughly along the lines of Refs. [KP91, Pol09, Kra01, Sen06, Tha92, Sch01].

2.1 Introduction

The basis of our investigations is *relativistic quantum mechanics.* This means that we are dealing with quantum mechanical models for a *finite* number of particles that are invariant under the transformations of the *Poincaré group*, the symmetry group of special relativity.

Any quantum mechanical model is formulated on a Hilbert space $\mathcal{H}$, i.e. a complete complex linear vector space with elements called *state vectors* in the quantum mechanical context. A state vector $|\Psi\rangle$ describes a particular state of a physical system. Experimentally measurable quantities, i.e. the observables of a physical system, correspond to expectation values and transition probabilities between such states. These quantities are determined by Hilbert-space scalar products. Hilbert-space scalar products are invariant under unitary transformations of the state vectors, which implies that probabilities are also unitarily invariant. Therefore, in order to ensure that probabilities are preserved under symmetry transformations of the system under consideration, one requires the action of a symmetry transformation on a state vector $|\Psi\rangle$ to be represented by a unitary operator.

According to the principles of special relativity the laws of physics are equivalent in all inertial coordinate systems. In other words, equivalent measurements done in different inertial coordinate systems lead to identical results. Inertial systems are connected by Poincaré transformations which form a group, the Poincaré group. In a theory where both relativity and quantum mechanics are incorporated, the principles of special relativity should be formulated in terms of quantum probabilities in such a way that quantum observables are invariant under the change of inertial reference systems. This is guaranteed if the effect of a Poincaré transformation on a state vector $|\Psi\rangle$ is represented by a unitary operator. In this way the only measurable quantities, namely probabilities, cannot be used to distinguish between different inertial coordinate systems [KP91]. This integration of special relativity into quantum theory was first realized by Wigner [Wig39]. A refined version of this theorem by Bargmann [Bar54] reads:

> *A quantum mechanical model formulated on a Hilbert space preserves probabilities in all inertial coordinate systems if and only if the correspondence between states in different inertial coordinate systems can be realized by a single-valued unitary representation of the covering group of the Poincaré group.*[1]

The purpose for requiring the covering group of the Poincaré group instead of the Poincaré group itself is to avoid ambiguities that appear when rotating half-integer spin particles through an angle of 2π [KP91]. By taking the covering group of the Poincaré group these unwanted ambiguities are removed (for a thorough discussion of this problem we refer, e.g., to Ref. [Tha92]).

2.2 The Poincaré Group

In this section we summarize the most important features of the symmetry group of special relativity, the Poincaré group. The theory of special relativity postulates the existence of inertial coordinate systems. These inertial systems are related by transformations that preserve the proper time τ_{12} between two events in Minkowski space. If these two events are described by the four-vectors x_1^μ and x_2^μ, τ_{12} is defined by

$$\tau_{12}^2 := (x_1 - x_2)^\mu \mathrm{g}_{\mu\nu} (x_1 - x_2)^\nu \, . \tag{2.1}$$

For the Minkowski-space conventions used throughout this work we refer to App. A.1. The transformations that leave Eq. (2.1) invariant form a group, the, so-called, *inhomogeneous Lorentz group* or *Poincaré group.* This group consists of the continuous one-parameter transformations of time translations, space translations, rotations and Lorentz boosts and the discrete transformations of time reversal, space inversion and four-dimensional reflections. The Poincaré group is the semi-direct product of the group $\mathbb{R}^4$ of space-time translations with the (homogeneous) Lorentz-group $\mathrm{O}(1,3)$ with elements Λ.[2] Consequently, a general Poincaré-group element is the pair (Λ, a) labeled by a Lorentz transformation Λ and a space-time translation a. The most general point transformation associated with (Λ, a) that satisfies Eq. (2.1) is given by

$$x^\mu \xrightarrow{(\Lambda,a)} x'^\mu = \Lambda^\mu{}_\nu x^\nu + a^\mu \, . \tag{2.2}$$

This transformation defines a representation of the Poincaré group in Minkowski space where a^μ is a constant four-vector and $\Lambda^\mu{}_\nu$ is a constant (4×4)-matrix. In the following we restrict ourselves to the continuous transformations which themselves form a subgroup of the Poincaré group, the so-called *proper, orthochronous* Poincaré group. It is the component of the Poincaré group containing the identity and it is characterized by the conditions $\det|\Lambda| = 1$ and ${\Lambda^0}_0 \geq 1$, referring to *proper* and *orthochronous*, respectively.[3]

---

[1] This theorem is often referred to as *the Wigner theorem.*

[2] $\mathrm{O}(1,3)$ is the linear group of Minkowski space $\mathbb{R}^{1+3}$ that leaves the scalar product, Eq. (2.1), invariant.

A rotation can be parametrized by a rotation axis and an angle of rotation described by the direction and the norm of the three-vector $\boldsymbol{\theta}$, respectively. In the (4×4)-matrix representation ${\Lambda^\mu}_\nu$ of the Lorentz group in Minkowski space a rotation is given by

$$R\,(\boldsymbol{\theta}) := \begin{pmatrix} 1 & 0 \\ 0 & \boldsymbol{R}\,(\boldsymbol{\theta}) \end{pmatrix} \tag{2.3}$$

with the usual SO(3) rotation matrix $\boldsymbol{R}\,(\boldsymbol{\theta})$.[4]

A canonical (rotationless) boost can be parametrized by a velocity $\boldsymbol{v}$ and is given in the above (4×4)-matrix representation in Minkowski space by

$$B_{\mathrm{c}}\,(\boldsymbol{v}) := \begin{pmatrix} v^0 & \boldsymbol{v}^{\mathrm{T}} \\ \boldsymbol{v} & \mathbf{1} + \frac{v^0 - 1}{\boldsymbol{v}^2}\boldsymbol{v}\,\boldsymbol{v}^{\mathrm{T}} \end{pmatrix} \tag{2.4}$$

with $v^0 = \sqrt{1 + \boldsymbol{v}^2}$. The velocity $\boldsymbol{v}$ can alternatively be expressed in terms of the rapidity $\boldsymbol{\rho}$ defined by $\boldsymbol{\rho} := \frac{\boldsymbol{v}}{|\boldsymbol{v}|} \sinh^{-1}|\boldsymbol{v}|$.[5]

At this point we introduce another type of boost associated with the helicity. It consists of a canonical boost in the three-direction to a desired magnitude $|\boldsymbol{v}|$, followed by a rotation into the desired direction $\hat{\boldsymbol{v}}$:[6]

$$B_{\mathrm{h}}\,(\boldsymbol{v}) := R\,(\boldsymbol{\theta})\,B_{\mathrm{c}}\,(|\boldsymbol{v}|\hat{\boldsymbol{x}}_3) \quad \text{with} \quad \boldsymbol{\theta} = \frac{\hat{\boldsymbol{x}}_3 \times \boldsymbol{v}}{|\hat{\boldsymbol{x}}_3 \times \boldsymbol{v}|} \cos^{-1}(\hat{\boldsymbol{x}}_3 \cdot \hat{\boldsymbol{v}})\,. \tag{2.5}$$

By expressing the matrices R and B_{c} in exponential form we can write down the most general proper Lorentz transformation, which can be decomposed into a rotation and a canonical boost according to the, so-called, *decomposition theorem* (a proof of this theorem can be found, e.g., in Ref. [Sch99]):

$$\Lambda\,(\boldsymbol{\theta}, \boldsymbol{\rho}) = \exp\left(-\mathrm{i}\,\boldsymbol{\theta} \cdot \boldsymbol{J}\right) \exp\left(-\mathrm{i}\,\boldsymbol{\rho} \cdot \boldsymbol{K}\right) \tag{2.6}$$

with the *generators* $\boldsymbol{J}$ and $\boldsymbol{K}$ for infinitesimal Lorentz transformations defined by

$$J^j := \mathrm{i}\left.\frac{\partial \Lambda\,(\boldsymbol{\theta}, \boldsymbol{\rho})}{\partial \theta^j}\right|_{\boldsymbol{\theta}=\boldsymbol{\rho}=0} \quad \text{and} \quad K^j := \mathrm{i}\left.\frac{\partial \Lambda\,(\boldsymbol{\theta}, \boldsymbol{\rho})}{\partial \rho^j}\right|_{\boldsymbol{\theta}=\boldsymbol{\rho}=0}, \quad j = 1, 2, 3\,. \tag{2.7}$$

These six infinitesimal Lorentz generators can be combined to six independent components of an antisymmetric tensor $M^{\mu\nu}$ of rank 2 which transforms covariantly under Lorentz transformations. This tensor is called the *angular momentum tensor* and its non-vanishing components are defined by $M^{ij} := \epsilon^{ijk} J^k$ and $M^{0j} := K^j$.

The inhomogeneous part of the Poincaré group, consisting of space-time translations, can be represented in (extended) Minkowski space by (5×5)-matrices. The infinitesimal generators for space-time translations are then given by

---

[3] We will use the terms *Poincaré group* and *Poincaré transformation* to refer only to the proper, orthochronous Poincaré group. Its homogeneous part is called the *proper, orthochronous* or *restricted* Lorentz group $\mathrm{SO}^+(1,3)$.

[4] SO(3) is the group of real (3×3)-matrices $\boldsymbol{R}$ with $\boldsymbol{R}^{\mathrm{T}} = \boldsymbol{R}^{-1}$ and $\det \boldsymbol{R} = 1$.

[5] Note that $\boldsymbol{v} := \frac{\mathrm{d}\boldsymbol{x}}{\mathrm{d}\tau} = v^0 \boldsymbol{v}_{\mathrm{ph}}$ with the *physical velocity* $\boldsymbol{v}_{\mathrm{ph}} = \frac{\mathrm{d}\boldsymbol{x}}{\mathrm{d}t}$ (see, e.g., Ref. [Sch99]).

[6] Here the 'hat' denotes a unit vector into the direction of the corresponding vector.

$$P^\mu := \mathrm{i}\,\mathrm{g}^{\mu\nu}\frac{\partial T(a)}{\partial a^\nu}\bigg|_{a^\nu=0} \tag{2.8}$$

with a space-time translation represented in (extended) Minkowski space by

$$T(a) := \begin{pmatrix} \mathrm{g}^\mu_\nu & a^\mu \\ 0^{\mathrm{T}\nu} & 1 \end{pmatrix}. \tag{2.9}$$

A detailed derivation can be found in App. A.2 or, e.g., in Ref. [Sch01].

The 10 infinitesimal generators of the Poincaré group in the (5 × 5)-matrix representation of Minkowski space satisfy a set of commutation relations, the, so-called. *Poincaré algebra.*[7] Its manifest covariant form reads

$$\begin{aligned} [P^\mu, P^\nu] &= 0\,, && (2.10)\\ [M^{\mu\nu}, P^\rho] &= \mathrm{i}\left(\mathrm{g}^{\nu\rho}P^\mu - \mathrm{g}^{\mu\rho}P^\nu\right), && (2.11)\\ \left[M^{\mu\nu}, M^{\lambda\sigma}\right] &= -\mathrm{i}\left(\mathrm{g}^{\mu\lambda}M^{\nu\sigma} - \mathrm{g}^{\nu\lambda}M^{\mu\sigma} + \mathrm{g}^{\nu\sigma}M^{\mu\lambda} - \mathrm{g}^{\mu\sigma}M^{\nu\lambda}\right). && (2.12) \end{aligned}$$

Eq. (2.10) are the commutation relations for the Abelian group of space-time translations, Eq. (2.11) ensures that P^μ transforms covariantly under Lorentz transformations and Eq. (2.12) is the Lie algebra of the Lorentz group.

2.3 The Covering Group of the Poincaré Group

2.3.1 Two-Spinor Representations

Remembering the Wigner theorem, the aim is to find a single-valued unitary representation of the covering group of the Poincaré group which acts on states of the Hilbert space. The covering group of Poincaré group is the inhomogeneous $\mathrm{SL}(2,\mathbb{C})$, also sometimes denoted as $\mathrm{ISL}(2,\mathbb{C})$, with the $\mathrm{SL}(2,\mathbb{C})$ being the covering group of the Lorentz group $\mathrm{SO}^+(1,3)$. It is the group of ordered pairs of complex (2×2)-matrices $(\underline{\Lambda}, \underline{a})$ with $\det\underline{\Lambda} = 1$ and $\underline{a} = \underline{a}^\dagger$.[8] The relation between the $\mathrm{ISL}(2,\mathbb{C})$ and the Poincaré group can be seen as follows. To this end we note that any four-vector x^μ can be represented by a 2 × 2 Hermitean matrix defined by [KP91]

$$\underline{x} := x^\mu\sigma_\mu \quad \Leftrightarrow \quad x^\mu = \frac{1}{2}\mathrm{tr}\left(\underline{x}\,\sigma_\mu\right) \tag{2.13}$$

with $\sigma_\mu := (\sigma^0, \boldsymbol{\sigma})$. Here $\sigma^0 \equiv 1_{2\times2}$ is the (2 × 2)-identity matrix and $\boldsymbol{\sigma} \equiv \{\sigma_i\}$ are the usual Pauli matrices defined in App. B.1.1. Note that here the usual Pauli matrices are defined via lower (covariant) indices. The relation to the proper time between two events, cf. Eq. (2.1), is then given by

$$\det|\underline{x}_1 - \underline{x}_2| = \tau_{12}^2\,. \tag{2.14}$$

---

[7] The Poincaré algebra is the Lie algebra of the corresponding Lie group, in our case the Poincaré group.

[8] The 'underline' of a symbol denotes an element of the $\mathrm{SL}(2,\mathbb{C})$.

The most general transformations that preserve this determinant (i.e. the proper time), the hermiticity of $\underline{x}$, the handedness of space and the direction of time read

$$\underline{x} \overset{(\underline{\Lambda},\underline{a})}{\longrightarrow} \underline{x}' = \underline{\Lambda}\,\underline{x}\,\underline{\Lambda}^\dagger + \underline{a}\,. \tag{2.15}$$

Then the connection to the Poincaré group elements (Λ, a) follows from Eq. (2.13):

$$\Lambda\,(\underline{\Lambda})^\mu{}_\nu = \frac{1}{2}\mathrm{tr}(\sigma_\mu\,\underline{\Lambda}\,\sigma_\nu\,\underline{\Lambda}^\dagger) \quad \text{and} \quad a^\mu = \frac{1}{2}\mathrm{tr}\,(\underline{a}\,\sigma_\mu)\;. \tag{2.16}$$

At this point we notice that each of the pairs $(\underline{\Lambda}, \underline{a})$ and $(-\underline{\Lambda}, \underline{a})$ correspond to the *same* Poincaré transformation $(\Lambda\,(\underline{\Lambda})\,, a) = (\Lambda\,(-\underline{\Lambda})\,, a)$. This means that there is a 2-to-1 correspondence between the $\mathrm{ISL}(2,\mathbb{C})$ and the Poincaré group. In other words, the group $\mathrm{ISL}(2,\mathbb{C})$ covers the Poincaré group twice. By identifying the elements $(\underline{\Lambda}, \underline{a})$ and $(-\underline{\Lambda}, \underline{a})$ in $\mathrm{ISL}(2,\mathbb{C})$ one obtains a group that is isomorphic to the Poincaré group [Pol09]. The most general $\underline{\Lambda}$ with $\det\underline{\Lambda} = 1$ can be written by the decomposition theorem as [KP91, Sch01]

$$\underline{\Lambda}\,(\boldsymbol{\theta}, \boldsymbol{\rho}) = \exp\left(\frac{1}{2}\boldsymbol{\rho}\cdot\boldsymbol{\sigma}\right)\exp\left(-\frac{\mathrm{i}}{2}\,\boldsymbol{\theta}\cdot\boldsymbol{\sigma}\right)\,. \tag{2.17}$$

In this, so-called, *spinor representation* of the $\mathrm{SL}(2,\mathbb{C})$ rotations are given by the unitary (2×2)-matrices

$$\underline{R}\,(\boldsymbol{\theta}) = \sigma^0 \cos\frac{\theta}{2} - \mathrm{i}\,\boldsymbol{\sigma}\cdot\hat{\boldsymbol{\theta}}\,\sin\frac{\theta}{2}\,, \tag{2.18}$$

whereas canonical boosts are given by the Hermitean (2×2)-matrices

$$\underline{B}_{\mathrm{c}}\,(\boldsymbol{\rho}) = \sigma^0 \cosh\frac{\rho}{2} + \boldsymbol{\sigma}\cdot\hat{\boldsymbol{\rho}}\,\sinh\frac{\rho}{2}\,. \tag{2.19}$$

In App. C.1 we have collected some useful relations for these $\mathrm{SL}(2,\mathbb{C})$ elements, which we will need for later purposes. According to the *polar decomposition theorem* any element of $\mathrm{SL}(2,\mathbb{C})$ can be written as a product of a unitary and a Hermitean matrix [RS72, KP91]. This corresponds to the decomposition theorem for Lorentz transformations. For the description of massive spin-$\frac{1}{2}$ particles there exist 2 different spinor representations of the $\mathrm{SL}(2,\mathbb{C})$: the representation $\underline{\Lambda}$ with generators

$$\underline{\boldsymbol{J}} = \frac{\boldsymbol{\sigma}}{2} \quad \text{and} \quad \underline{\boldsymbol{K}} = \mathrm{i}\,\frac{\boldsymbol{\sigma}}{2} \tag{2.20}$$

which we have already introduced in Eq. (2.17) and another, inequivalent representation defined by $\underline{\Lambda}' := (\underline{\Lambda}^\dagger)^{-1}$ with generators

$$\underline{\boldsymbol{J}}' = \frac{\boldsymbol{\sigma}}{2} \quad \text{and} \quad \underline{\boldsymbol{K}}' = -\mathrm{i}\,\frac{\boldsymbol{\sigma}}{2}\,. \tag{2.21}$$

These two spinor representations $\underline{\Lambda}$ and $\underline{\Lambda}'$ are called the *right-* and the *left-handed representation*, respectively. They are not equivalent but connected by space inversion [Sch01].

2.3.2 Four-Spinor Representation

The fact that there is no element of $\mathrm{SL}(2,\mathbb{C})$ corresponding to space inversion requires to double the dimension of the representation space in order to obtain a matrix representation of the Poincaré group. A direct sum (up to a similarity transformation) of the right- and left-handed representation gives a linear matrix representation on $\mathbb{C}^4$. Consequently, combining the matrices $\underline{\Lambda}$ and $(\underline{\Lambda}^\dagger)^{-1}$ into a (4×4)-matrix gives [Tha92]

$$S\left(\underline{\Lambda}\right) = \begin{pmatrix} \underline{\Lambda} & 0 \\ 0 & (\underline{\Lambda}^\dagger)^{-1} \end{pmatrix} . \tag{2.22}$$

In this (4×4)-matrix representation of the Lorentz group a general Lorentz transformation is given by [Gro93]

$$S\left(\underline{\Lambda}\left(\boldsymbol{\theta},\boldsymbol{\rho}\right)\right) = \exp\left[\frac{1}{2}\left(-\mathrm{i}\,\gamma^5\boldsymbol{\theta}+\boldsymbol{\rho}\right)\cdot\boldsymbol{\alpha}\right] . \tag{2.23}$$

Then a rotation and a canonical boost read

$$S\left(\underline{R}\left(\boldsymbol{\theta}\right)\right) = 1_4\cos\frac{\theta}{2} - \mathrm{i}\,\gamma^5\boldsymbol{\alpha}\cdot\hat{\boldsymbol{\theta}}\sin\frac{\theta}{2} \tag{2.24}$$

and

$$S\left(\underline{B}_{\mathrm{c}}\left(\boldsymbol{\rho}\right)\right) = 1_4\cosh\frac{\rho}{2} + \boldsymbol{\alpha}\cdot\hat{\boldsymbol{\rho}}\sinh\frac{\rho}{2} , \tag{2.25}$$

respectively, with

$$1_4 := 1_{4\times 4} \quad \text{and} \quad \boldsymbol{\alpha} := \begin{pmatrix} \boldsymbol{\sigma} & 0 \\ 0 & \boldsymbol{\sigma} \end{pmatrix} . \tag{2.26}$$

The representation of $\boldsymbol{\alpha}$ given by Eq. (2.26) was already determined by the choice of the representation of $S\left(\underline{\Lambda}\right)$ given by Eq. (2.22). A similarity transformation transforms the representation of Eq. (2.26) into another representation, the, so-called, *standard representation* defined in App. B.1.1. We will use the standard representation throughout the present work.

2.3.3 Unitary Representation

According to the Wigner theorem we have to find a single-valued unitary representation of the $\mathrm{ISL}(2,\mathbb{C})$ acting on $\mathcal{H}$, which will be denoted by $\hat{U}$.[9] $\hat{U}$ is a mapping from the $\mathrm{ISL}(2,\mathbb{C})$ to the space of linear operators on the quantum mechanical Hilbert space $\mathcal{H}$ and can be written in an exponential form as [KP91]

$$\hat{U}\left(\underline{\Lambda}\left(\boldsymbol{\theta},\boldsymbol{\rho}\right),\underline{a}\right) = \exp(-\mathrm{i}\,\hat{P}\cdot a)\,\exp(-\mathrm{i}\,\hat{\boldsymbol{J}}\cdot\boldsymbol{\theta} - \mathrm{i}\,\hat{\boldsymbol{K}}\cdot\boldsymbol{\rho}) . \tag{2.27}$$

The infinitesimal generators of this unitary representation of the $\mathrm{ISL}(2,\mathbb{C})$ are self-adjoint operators given by

$$\hat{J}^j = \mathrm{i}\left.\frac{\partial\hat{U}\left(\underline{R}\left(\boldsymbol{\theta}\right)\right)}{\partial\theta^j}\right|_{\boldsymbol{\theta}=0} , \quad \hat{K}^j = \mathrm{i}\left.\frac{\partial\hat{U}\left(\underline{B}_{\mathrm{c}}\left(\boldsymbol{\rho}\right)\right)}{\partial\rho^j}\right|_{\boldsymbol{\rho}=0} , \tag{2.28}$$

$$\text{and} \quad \hat{P}^\mu = \mathrm{i}\,\mathrm{g}^{\mu\nu}\left.\frac{\partial\hat{U}\left(\underline{a}\right)}{\partial a^\nu}\right|_{a^\nu=0} . \tag{2.29}$$

---

[9] Here the 'hat' on the top of a symbol denotes an *operator* acting on $\mathcal{H}$ and *not* a unit vector, but despite of this ambiguity in the notation the distinction between unit vectors and Hilbert-space operators should be clear from the context.

The generators $\hat{\boldsymbol{J}}$, $\hat{\boldsymbol{P}}$ and $\hat{P}^0$ have the familiar interpretations as physical quantities of the system under consideration: the generator for rotations $\hat{\boldsymbol{J}}$ is the total angular momentum operator, the generator for space translations $\hat{\boldsymbol{P}}$ is the total linear momentum operator, and the generator for time translations $\hat{P}^0$ represents the total energy of the system (note that the boost generator $\hat{\boldsymbol{K}}$ has no physical interpretation as observable) [KP91].

Using the group representation property it can be shown that these operators satisfy the Poincaré algebra, Eqs. (2.10)-(2.12). Furthermore, they have the following transformation properties under Poincaré transformations [Pol09]:

$$\begin{aligned} \hat{U}^\dagger\left(\underline{\Lambda}, \underline{a}\right) \hat{P}^\mu \hat{U}\left(\underline{\Lambda}, \underline{a}\right) &= \Lambda^\mu{}_\nu \hat{P}^\nu \,, && (2.30) \\ \hat{U}^\dagger\left(\underline{\Lambda}, \underline{a}\right) \hat{M}^{\mu\nu} \hat{U}\left(\underline{\Lambda}, \underline{a}\right) &= \Lambda^\mu{}_\sigma \Lambda^\nu{}_\tau \left(\hat{M}^{\sigma\tau} - a^\sigma \hat{P}^\tau + a^\tau \hat{P}^\sigma\right) . && (2.31) \end{aligned}$$

2.4 Casimir Operators and Newton-Wigner Position Operator

This section is devoted to the Hilbert-space representation of the Casimir operators of the Poincaré group and to the Newton-Wigner position operator. The Casimir operators (operator invariants) of the Poincaré group are defined as the only independent self-adjoint operators, being polynomials in the Poincaré generators, that commute with every Poincaré generator. The states of an irreducible representation of the Poincaré group must be eigenstates of the Casimir operators. Therefore, their eigenvalues can be used to classify different types of irreducible representations [KP91, Sca07]. In particular, we will see that these quantum numbers are the mass and the spin of a system associated with the eigenvalues of a mass operator and a spin operator, respectively. For later purposes we will also define a position operator, i.e. the canonically conjugate operator to the three-momentum operator.

2.4.1 The Mass Operator

The mass operator squared $\hat{M}^2$ is defined as the square of the four-momentum operator $\hat{P}^\mu$:

$$\hat{M}^2 := \hat{P}^\mu \hat{P}_\mu \,. \tag{2.32}$$

It is self-adjoint, commutes with every generator and is therefore a Casimir operator of the Poincaré group. The, so-called, *spectral condition* requires $\hat{M}^2$ to have only non-negative eigenvalues [KP91]. Then the square root of this operator can be defined as the operator

$$\hat{M} := \sqrt{\hat{P}^\mu \hat{P}_\mu} \,. \tag{2.33}$$

The eigenvalue of $\hat{M}$ will be called the *physical mass* of the system.

2.4.2 The Spin Operator

In addition to the mass operator we can construct a second Casimir operator from the generators of the Poincaré group. To this aim we introduce the, so-called, *Pauli-Lubanski operator* $\hat{W}^\mu$ by

$$\hat{W}^\mu := -\frac{1}{2}\epsilon^{\mu\nu\sigma\tau}\hat{P}_\nu \hat{M}_{\sigma\tau}\,, \tag{2.34}$$

which is again a self-adjoint operator. $\hat{W}^\mu$ satisfies the following commutation relations [KP91]:

$$\begin{aligned} \left[\hat{W}^\mu, \hat{P}^\nu\right] &= 0\,, & (2.35)\\ \left[\hat{M}^{\mu\nu}, \hat{W}^\rho\right] &= \mathrm{i}\left(\mathrm{g}^{\nu\rho}\hat{W}^\mu - \mathrm{g}^{\mu\rho}\hat{W}^\nu\right)\,, & (2.36)\\ \left[\hat{W}^\mu, \hat{W}^\nu\right] &= \mathrm{i}\,\epsilon^{\mu\nu\sigma\tau}\hat{W}_\sigma \hat{P}_\tau\,. & (2.37) \end{aligned}$$

Eq. (2.36) ensures that $\hat{W}^\mu$ transforms like a four-vector under Lorentz transformations, cf. Eq. (2.30). Therefore, its square is a Lorentz invariant and given by

$$\hat{W}_\mu \hat{W}^\mu = -\hat{M}^2 \hat{\boldsymbol{J}}_\mathrm{g}^2\,, \tag{2.38}$$

where $\hat{\boldsymbol{J}}_\mathrm{g}$ is the total *intrinsic spin operator*. $\hat{\boldsymbol{J}}_\mathrm{g}^2$ is independent of $\hat{M}^2$, commutes with all the Poincaré generators and is therefore (beside $\hat{M}^2$) the second Casimir operator of the Poincaré group.

From the definition of $\hat{W}^\mu$, cf. Eq. (2.34), we find the Lorentz invariant relation

$$\hat{P}_\mu \hat{W}^\mu = 0\,. \tag{2.39}$$

This equation implies that $\hat{W}^\mu$ must be a space-like vector since $\hat{P}^\mu$ is time-like by the spectral condition. Any space-like vector can be Lorentz transformed into a reference frame where its time component vanishes. Eq. (2.39) implies that this transformation is a *general Lorentz boost* into the rest frame of the system. This boost is denoted by $B_\mathrm{g}^{-1}(\hat{\boldsymbol{V}})$ where $\hat{V}^\mu := \hat{P}^\mu/\hat{M}$ is the four-velocity operator. $B_\mathrm{g}^{-1}(\hat{\boldsymbol{V}})$ together with Eq. (2.38) can be used to define a spin operator $\hat{\boldsymbol{J}}_\mathrm{g}$ by[10]

$$(0, \hat{\boldsymbol{J}}_\mathrm{g})^\mu = \frac{1}{\hat{M}} B_\mathrm{g}^{-1}(\hat{\boldsymbol{V}})^\mu{}_\nu \hat{W}^\nu\,. \tag{2.40}$$

It should be mentioned that this expression does not transform like a four-vector under Lorentz transformations. It rather transforms with a, so-called, *Wigner rotation* $R_{\mathrm{W}_\mathrm{g}}$:

$$\hat{U}^\dagger(\underline{\Lambda}, \underline{a})\,(0, \hat{\boldsymbol{J}}_\mathrm{g})^\mu\,\hat{U}(\underline{\Lambda}, \underline{a}) = R_{\mathrm{W}_\mathrm{g}}(\hat{V}, \Lambda)^\mu{}_\nu (0, \hat{\boldsymbol{J}}_\mathrm{g})^\nu \tag{2.41}$$

with

$$R_{\mathrm{W}_\mathrm{g}}(V, \Lambda) := B_\mathrm{g}^{-1}(\boldsymbol{\Lambda} V)\,\Lambda\,B_\mathrm{g}(\boldsymbol{V})\,. \tag{2.42}$$

The proof of Eq. (2.41) can be found, e.g., in Ref. [Pol09].

---

[10] The spin operator $\hat{\boldsymbol{J}}_\mathrm{g}$ can equivalently be defined via the angular momentum tensor operator $\hat{M}^{\mu\nu}$ by the relation $\hat{J}_\mathrm{g}^i = \frac{1}{2}\epsilon^{ikl} B_\mathrm{g}^{-1}(\hat{\boldsymbol{V}})^k{}_\mu B_\mathrm{g}^{-1}(\hat{\boldsymbol{V}})^l{}_\nu \hat{M}^{\mu\nu}$ [KP91].

The definition of $\hat{\boldsymbol{J}}_{\rm g}$ in Eq. (2.40) is still not unique, since there exist in principle infinite many different boosts (combinations of rotationless boosts and rotations) that transform a system with a given momentum $\hat{P}^\mu$ into its rest frame with momentum $(\hat{M}, \boldsymbol{0})^\mu$. Note that Lorentz invariance of Eq. (2.38) implies that the square of the spin operator is independent of the particular choice of the boost $B_{\rm g}^{-1}(\hat{\boldsymbol{V}})$ and therefore unique. In case $B_{\rm g}^{-1}(\hat{\boldsymbol{V}})$ is a canonical (rotationless) boost $B_{\rm c}^{-1}(\hat{\boldsymbol{V}})$ (cf. Eq. (2.4)), then Eq. (2.40) defines the *canonical spin operator* $\hat{\boldsymbol{J}}_{\rm c}$:

$$\left(0, \hat{\boldsymbol{J}}_{\rm c}\right)^\mu := \frac{1}{\hat{M}} B_{\rm c}^{-1}(\hat{\boldsymbol{V}})^\mu{}_\nu \hat{W}^\nu \,. \tag{2.43}$$

Only this canonical spin operator $\hat{\boldsymbol{J}}_{\rm c}$ transforms like a three-vector under rotations, since Wigner rotations for canonical boosts have the special property that

$$R_{\rm W_c}(V, R) = R \tag{2.44}$$

where R is a rotation.[11] Therefore, the canonical Wigner rotation of a rotation is the rotation itself. The proof of Eq. (2.44) can be found, e.g., in Refs. [Kli98b, Pol09]. If a helicity boost is used in Eq. (2.40) to define the spin we speak of a *helicity spin operator* $\hat{\boldsymbol{J}}_{\rm h}$, because its third component is the familiar expression for the helicity:

$$\hat{J}^3_{\rm h} = \frac{\hat{\boldsymbol{P}} \cdot \hat{\boldsymbol{J}}}{|\hat{\boldsymbol{P}}|} \,. \tag{2.45}$$

The special property of the helicity is that it has a well-defined value in the limit of a vanishing mass.

Using Eq. (2.37) together with the spectral condition on $\hat{M}^2$ we obtain the usual SU(2) Lie algebra for the spin operators:[12]

$$\left[\hat{J}^i_{\rm g}, \hat{J}^k_{\rm g}\right] = {\rm i}\epsilon^{ikl} \hat{J}^l_{\rm g}. \tag{2.46}$$

These relations imply that the spin eigenvalue J can only be an integer or a half-integer number. In the case of the helicity spin the SU(2) commutation relations are satisfied by the components $\hat{J}^3_{\rm h}$ and $\hat{\boldsymbol{J}}_{\rm h} \times \boldsymbol{x}_3 / |\boldsymbol{x}_3|$.

2.4.3 Newton-Wigner Position Operator

For the case of canonical spin one finds by direct computation that $\hat{\boldsymbol{J}}_{\rm c}$ is related to the Lorentz generators by

$$\hat{\boldsymbol{J}} = \hat{\boldsymbol{X}}_{\rm c} \times \hat{\boldsymbol{P}} + \hat{\boldsymbol{J}}_{\rm c} \tag{2.47}$$

and

$$\hat{\boldsymbol{K}} = -\frac{1}{2}\{\hat{P}^0, \hat{\boldsymbol{X}}_{\rm c}\} - \frac{\hat{\boldsymbol{P}} \times \hat{\boldsymbol{J}}_{\rm c}}{\hat{P}^0 + \hat{M}} \,. \tag{2.48}$$

---

[11] Note that Eq. (2.44) implies the relation $R\, B_{\rm c}(\boldsymbol{V})\, R^{-1} = B_{\rm c}(\boldsymbol{R}V)$.

[12] SU(2) is the group of (2×2)-matrices $\underline{R}$ with $\underline{R}^\dagger = \underline{R}^{-1}$ and $\det|\underline{R}| = 1$. It is the universal covering group of the rotation group SO(3).

Here the Hermitean operator $\hat{\boldsymbol{X}}_{\mathrm{c}}$ is the canonically conjugate operator to $\hat{\boldsymbol{P}}$ and given by

$$\hat{\boldsymbol{X}}_{\mathrm{c}} = -\frac{1}{2}\{\frac{1}{\hat{P}^0},\hat{\boldsymbol{K}}\} - \frac{\hat{\boldsymbol{P}}\times(\hat{P}^0\hat{\boldsymbol{J}} - \hat{\boldsymbol{P}}\times\hat{\boldsymbol{K}})}{\hat{P}^0\hat{M}(\hat{P}^0+\hat{M})}\,. \tag{2.49}$$

It was introduced by Newton and Wigner in Ref. [NW49] and is called the *Newton-Wigner position operator*. The role of this operator will become evident later when dealing with the construction of dynamical representations of the Poincaré group.

It should be mentioned that the above relation between the canonical spin operator $\hat{\boldsymbol{J}}_{\mathrm{c}}$ and the total angular momentum $\hat{\boldsymbol{J}}$ is equivalent to the corresponding relation in non-relativistic quantum mechanics. This is special to canonical spins and allows one to couple spin and orbital angular momentum to the total angular momentum using the standard addition rules of combining angular momenta in non-relativistic quantum mechanics [KP91].

2.5 One-Particle Irreducible Representations

The aim of this section is to end up with a Poincaré-invariant quantum mechanical description of a single particle with mass m and spin j. This amounts to finding an irreducible representation of the Poincaré group on a one-particle Hilbert space. The eigenvalues m^2 and $j(j+1)$ of the Casimirs $\hat{m}^2$ and $\hat{\boldsymbol{j}}^2$, respectively, together with the sign of the eigenvalue p^0 of the Hamiltonian $\hat{p}^0$ can be used to classify irreducible representations [Pol09]. In the present work we will only consider the massive spin-j case with $m^2 > 0$ and $p^0 > 0$ and the massless spin-1 case with $m^2 = 0$ and $p^0 > 0$.

2.5.1 Massive Representations

We start with massive particles. A suitable basis for a one-particle Hilbert-space representation is given by the set of simultaneous eigenstates $|m, j, \boldsymbol{p}, \sigma\rangle$ of the commuting Hermitean one-body operators

$$\hat{m}^2, \quad \hat{\boldsymbol{j}}^2, \quad \hat{\boldsymbol{p}} \quad \text{and} \quad \hat{j}^3_{\mathrm{c}}\,. \tag{2.50}$$

For the states $|m, j, \boldsymbol{p}, \sigma\rangle$ short-hand denoted as $|\boldsymbol{p}, \sigma\rangle$ we use a covariant normalization given by

$$\langle \boldsymbol{p}', \sigma' | \boldsymbol{p}, \sigma\rangle = (2\pi)^3 \delta_{\sigma\sigma'} 2p^0 \delta^3(\boldsymbol{p} - \boldsymbol{p}')\ . \tag{2.51}$$

The corresponding completeness relation reads

$$\hat{1} = \int_{\mathbb{R}^3} \frac{\mathrm{d}^3 p}{(2\pi)^3 2p^0} \sum_{\sigma=-j}^{j} |\boldsymbol{p}, \sigma\rangle\langle \boldsymbol{p}, \sigma|\,. \tag{2.52}$$

The action of $\hat{U}(\underline{\mathit{\Lambda}}, \underline{a})$ on $|\boldsymbol{p}, \sigma\rangle$ is given by

$$\hat{U}(\underline{\mathit{\Lambda}}, \underline{a})\,|\boldsymbol{p}, \sigma\rangle \quad = \quad \exp(-\mathrm{i}\mathit{\Lambda} p\cdot a) \sum_{\sigma'=-j}^{j} D^j_{\sigma'\sigma}\left[\underline{R}_{\mathrm{W_c}}(v, \mathit{\Lambda})\right] |\boldsymbol{\Lambda} p, \sigma'\rangle\,, \tag{2.53}$$

with $v = p/m$. For a detailed derivation of Eq. (2.53) see, e.g., Ref. [KP91]. Here

$$D^{j}_{\sigma'\sigma}(\underline{R}) := \langle j, \sigma' | \hat{U}\,(\underline{R}, 0)\,| j, \sigma\rangle \tag{2.54}$$

are the familiar *Wigner D-functions* being a $(2j+1)$ dimensional unitary irreducible representation of the rotation group SU(2) in the basis $|j,\sigma\rangle \equiv |\sigma\rangle$ (see, e.g., Ref. [VMK88]). Some useful relations of these Wigner D-functions which will be repeatedly used throughout this work are collected in App. (C.2).

2.5.2 Massless Representations for Spin-1 Particles

In this section we turn to the case of massless particles with $m^2 = 0$. For a detailed discussion on the covariant treatment of massless spin-1 particles, such as the photon γ, within the so-called *Gupta-Bleuler formalism* see, e.g. Refs. [Ble50, Gup50, Sch61, Kli03b]. A suitable basis for massless spin-1 states is given by the state vectors $|j, \boldsymbol{p}, \lambda\rangle \equiv |\boldsymbol{p}, \lambda\rangle$ with λ denoting the 4 polarization degrees-of-freedom of a massless vector field (2 physical and 2 unphysical ones). These states are simultaneous eigenstates of the operators

$$\hat{\boldsymbol{j}}^2, \quad \hat{\boldsymbol{p}} \quad \text{and} \quad \hat{j}^3_{\mathrm{h}}\,. \tag{2.55}$$

These massless states are normalized covariantly according to

$$\langle \boldsymbol{p}', \lambda' | \boldsymbol{p}, \lambda\rangle = (2\pi)^3 (-\mathrm{g}_{\lambda\lambda'}) 2|\boldsymbol{p}| \delta^3\left(\boldsymbol{p} - \boldsymbol{p}'\right) . \tag{2.56}$$

The corresponding completeness relation reads

$$\hat{1} = \int_{\mathbb{R}^3} \frac{\mathrm{d}^3 p}{(2\pi)^3 2|\boldsymbol{p}|} \sum_{\lambda=0}^{3} (-\mathrm{g}_{\lambda\lambda}) |\boldsymbol{p}, \lambda\rangle\langle \boldsymbol{p}, \lambda|\,. \tag{2.57}$$

The transformation properties of $|\boldsymbol{p}, \lambda\rangle$ under Poincaré transformations are given by

$$\hat{U}(\underline{\Lambda}, \underline{a}) |\boldsymbol{p}, \lambda\rangle = \exp\left(-\mathrm{i}\Lambda p \cdot a\right) \sum_{\lambda'=0}^{3} R_{\mathrm{W_h}}\left(p, \Lambda\right)_{\lambda'\lambda} |\boldsymbol{\Lambda} p, \lambda'\rangle \tag{2.58}$$

where

$$R_{\mathrm{W_h}}\left(p, \Lambda\right) := B_{\mathrm{h}}^{-1}(\boldsymbol{\Lambda} p)\, \Lambda\, B_{\mathrm{h}}(\boldsymbol{p}) \tag{2.59}$$

is the massless analogue of a Wigner rotation.

2.6 Multi-Particle Representations

After having found the one-particle irreducible representations of the Poincaré group in the previous section we consider now systems with more than 1 particle. We will restrict our considerations to a finite number of degrees of freedom. Our aim is to end up with a multi-particle representation of the Poincaré group which is constructed from the one-particle irreducible representations. In particular, we will use two different kinds of multi-particle bases, the tensor-product-state and the velocity-state basis.

2.6.1 Tensor-Product States

The first step towards a multi-particle representation of the Poincaré group is to consider a n-particle Hilbert space which is the n-fold tensor product of single-particle Hilbert spaces of the previous section. A free n-particle momentum state basis of this n-particle Hilbert space is then constructed from tensor products of n single-particle basis states as follows:

$$|\boldsymbol{p}_1,\sigma_1;\boldsymbol{p}_2,\sigma_2;\ldots;\boldsymbol{p}_n,\sigma_n\rangle \equiv |\{\boldsymbol{p}_i,\sigma_i\}\rangle := |\boldsymbol{p}_1,\sigma_1\rangle \otimes |\boldsymbol{p}_2,\sigma_2\rangle \otimes \ldots \otimes |\boldsymbol{p}_n,\sigma_n\rangle \,. \tag{2.60}$$

Here p_i^μ and σ_i are the physical four-momentum and canonical spin projection of the i^{th} particle, respectively. We assume that all single particles are on their respective mass shells, i.e.

$$p_i^0 = \sqrt{m_i^2 + \boldsymbol{p}_i^2}\,, \quad \forall\, i = 1,\ldots,n\,. \tag{2.61}$$

The kinematic variables

$$P_n^\mu = \sum_{i=1}^n p_i^\mu \quad \text{and} \quad M_n = \sqrt{P_n^2} \tag{2.62}$$

are the free total four-momentum and the free invariant mass of the n-particle system, respectively. A unitary representation of the Poincaré group acting on the tensor-product states (2.60) is given by a tensor product of n irreducible single-particle representations:

$$\hat{U}_{12\cdots n}\left[\underline{\Lambda},\underline{a}\right] := \hat{U}_1\left[\underline{\Lambda},\underline{a}\right] \otimes \hat{U}_2\left[\underline{\Lambda},\underline{a}\right] \otimes \ldots \otimes \hat{U}_n\left[\underline{\Lambda},\underline{a}\right]\,. \tag{2.63}$$

Consequently, the Poincaré generators of the n-particle system are sums of the n one-particle generators:

$$\begin{aligned} \hat{P}_n^\mu \;&:=\; \hat{p}_1^\mu \otimes \hat{1}_2 \otimes \cdots \otimes \hat{1}_n + \hat{1}_1 \otimes \hat{p}_2^\mu \otimes \cdots \otimes \hat{1}_n + \ldots + \hat{1}_1 \otimes \hat{1}_2 \otimes \cdots \otimes \hat{p}_n^\mu\,; \\ \hat{M}_n^{\mu\nu} \;&:=\; \hat{m}_1^{\mu\nu} \otimes \hat{1}_2 \otimes \cdots \otimes \hat{1}_n + \hat{1}_1 \otimes \hat{m}_2^{\mu\nu} \otimes \cdots \otimes \hat{1}_n + \ldots \\ &\quad\; + \hat{1}_1 \otimes \hat{1}_2 \otimes \cdots \otimes \hat{m}_n^{\mu\nu}\,. \end{aligned} \tag{2.64}$$

The transformation properties of the multi-particle tensor-product states under Poincaré transformations follow from the corresponding transformation properties of the single-particle states, cf. Eqs. (2.53) and (2.58):

$$\hat{U}_{12\cdots n}\left[\underline{\Lambda},\underline{a}\right]|\{\boldsymbol{p}_i,\sigma_i\}\rangle = \mathrm{e}^{-\mathrm{i}\Lambda P_n\cdot a}\sum_{\{\sigma_i\}}|\{\boldsymbol{\Lambda}p_i,\sigma_i'\}\rangle \prod_{i=1}^n D^{j_i}_{\sigma_i'\sigma_i}\left[\underline{R}_{\mathrm{W_c}}\left(v_i,\Lambda\right)\right] \tag{2.65}$$

where $v_i := p_i/m_i$ is the four-velocity of the i^{th} particle.

2.6.2 Velocity States

In this section we will introduce another, alternative basis for multi-particle states which is associated with the overall and internal motion of the multi-particle system. To be more precise, we will define a multi-particle state which is specified by the overall free four-velocity of the n-particle system

$$V^\mu := \frac{P_n^\mu}{M_n} \tag{2.66}$$

and the individual center-of-mass momenta

$$k_i := B_{\mathrm{c}}^{-1}(\boldsymbol{V})\,p_i\,, \quad i = 1, \ldots, n\,. \tag{2.67}$$

Note that the n center-of-mass momenta $\boldsymbol{k}_1, \ldots, \boldsymbol{k}_n$ are not independent from each other but constrained by the relation

$$\sum_{i=1}^{n} \boldsymbol{k}_i = 0\,. \tag{2.68}$$

Thus, the center-of-mass momentum of the j^{th} particle $\boldsymbol{k}_j$ can be expressed in terms of the remaining $n-1$ center-of-mass momenta.

A multi-particle state characterized by V and by the $n-1$ $\{\boldsymbol{k}_i\}$ will be called a *velocity state*. It was introduced by Klink in Ref. [Kli98b]. Such a velocity state is defined by applying a canonical boost $\hat{U}_{12\cdots n}\left[\underline{B}_{\mathrm{c}}(\boldsymbol{V})\right]$ to the multi-particle rest state:

$$\begin{aligned} &|V; \boldsymbol{k}_1, \mu_1; \boldsymbol{k}_2, \mu_2; \ldots; \boldsymbol{k}_n, \mu_n\rangle \equiv |V; \{\boldsymbol{k}_i, \mu_i\}\rangle \\ &:= \quad \hat{U}_{12\cdots n}\left[\underline{B}_{\mathrm{c}}(\boldsymbol{V})\right] |\{\boldsymbol{k}_i, \mu_i\}\rangle = \sum_{\{\sigma_i\}} |\{\boldsymbol{p}_i, \sigma_i\}\rangle \prod_{i=1}^{n} D^{j_i}_{\sigma_i \mu_i}\left[\underline{R}_{\mathrm{W_c}}(w_i, B_{\mathrm{c}}(\boldsymbol{V}))\right] \end{aligned} \tag{2.69}$$

with the internal four-velocities defined by $w_i := k_i/m_i$. μ_i denotes the canonical spin projection of the i^{th} particle associated with the multi-particle state in the rest frame.

The action of the four momentum operator on this velocity state can be easily evaluated using the transformation properties of $\hat{P}^\mu$, Eq. (2.30):

$$\hat{P}^\mu_n |V; \{\boldsymbol{k}_i, \mu_i\}\rangle = M_n V^\mu |V; \{\boldsymbol{k}_i, \mu_i\}\rangle\,, \tag{2.70}$$

where $M_n = \sum_{i=1}^n k_i^0$. Therefore, a velocity state $|V; \{\boldsymbol{k}_i, \mu_i\}\rangle$ is an eigenstate of $\hat{P}^\mu_n$ with eigenvalue $M_n V^\mu$. This suggests writing $\hat{P}^\mu_n$ as the product

$$\hat{P}^\mu_n = \hat{M}_n \hat{V}^\mu \tag{2.71}$$

where

$$\hat{M}_n = \sqrt{\hat{P}^\mu_n \hat{P}_{n\mu}} \quad \text{and} \quad \hat{V}^\mu := \frac{\hat{P}^\mu_n}{\hat{M}_n} \tag{2.72}$$

are the free invariant mass operator and the free four-velocity operator, respectively. $\hat{V}^\mu$ transforms like a four-vector operator under Lorentz transformations and satisfies the relation $\hat{V}^\mu \hat{V}_\mu = \hat{1}$. A velocity state $|V; \{\boldsymbol{k}_i, \mu_i\}\rangle$ is a simultaneous eigenstate of $\hat{M}_n$ and $\hat{V}^\mu$ with eigenvalues $M_n = \sum_{i=1}^n k_i^0$ and $V^\mu = (\sqrt{1+\boldsymbol{V}^2}, \boldsymbol{V})$, respectively. $|V; \{\boldsymbol{k}_i, \mu_i\}\rangle$ is also an eigenstate of the center-of-mass momentum operators $\hat{k}^\mu_i$. These operators do not transform covariantly under Lorentz transformations; rather they transform under a Wigner rotation in the same way as the spin operator $(0, \hat{\boldsymbol{J}}_{\mathrm{g}})^\mu$, cf. Eq. (2.41).

The transformation properties of the velocity states under Lorentz transformations are given by

$$\begin{aligned} &\hat{U}_{12\cdots n}(\underline{\Lambda})\, |V; \{\boldsymbol{k}_i, \mu_i\}\rangle \\ &\quad = \sum_{\{\mu'_i\}} |\Lambda V; \{\boldsymbol{R}_{\mathrm{W_c}}(V, \Lambda) k_i, \mu'_i\}\rangle \prod_{i=1}^{n} D^{j_i}_{\mu'_i \mu_i}\left[\underline{R}_{\mathrm{W_c}}(V, \Lambda)\right]\,. \end{aligned} \tag{2.73}$$

For each *massless* spin-1 particle occurring in the velocity state the corresponding Wigner D-function has to be replaced by the (4×4)-dimensional Minkowski-space representation of the Lorentz group (cf. Eq. (2.3)):

$$D^{j_i}_{\mu_i'\mu_i}\left[\underline{R}_{\mathrm{W_c}}\left(V,\varLambda\right)\right] \to R_{\mathrm{W_h}}\left[k_i, R_{\mathrm{W_c}}(V,\Lambda)\right]_{\mu_i'\mu_i} . \tag{2.74}$$

A comparison of the transformation properties of the tensor-product states, Eq. (2.65), with those of the velocity states, Eq. (2.73), leads to the following notable observation: for tensor-product states each Wigner rotation in the D-functions depends on a *different* single-particle four-velocity v_i, whereas for velocity states all momenta and canonical spins rotate with the *same* Wigner rotation as a consequence of Eq. (2.44). This property of the velocity states makes it possible to couple canonical spins and orbital angular momenta according to the standard addition rules using SU(2) Clebsch-Gordan coefficients [Kli98b].

The transformation properties of a velocity state under a space-time translation $\hat{U}_{12\cdots n}\left(\underline{a}\right)$ are equivalent with those for a tensor-product state if one identifies P_n^μ with $M_n V^\mu$ in the exponent of Eq. (2.65):

$$\hat{U}_{12\cdots n}\left(\underline{a}\right)|V;\{\boldsymbol{k}_i,\mu_i\}\rangle = |V;\{\boldsymbol{k}_i,\mu_i\}\rangle \mathrm{e}^{-\mathrm{i}M_n V\cdot a} . \tag{2.75}$$

Orthogonality and completeness relations for the velocity states can be derived from the ones for the usual tensor-product states. To this we have to transform the corresponding integral measures for a system of n particles according

$$\int \prod_{i=1}^{n} \frac{\mathrm{d}^3 p_i}{2p_i^0} = \int \frac{\mathrm{d}^3 V}{V^0} \prod_{i=1}^{n-1} \frac{\mathrm{d}^3 k_i}{2k_i^0} \frac{(\sum_{j=1}^{n} k_j^0)^3}{2k_n^0} , \tag{2.76}$$

where $k_i^0 := \sqrt{m_i^2+\boldsymbol{k}_i^2}$ for $\forall\, i = 1,\ldots,n-1$ and $k_n^0 := \sqrt{m_n^2+(\sum_{j=1}^{n-1}\boldsymbol{k}_j)^2}$. Here the n^{th} momentum has been chosen to be redundant without loss of generality. Then the completeness relation for the velocity states follows from the one for the tensor-product states:

$$\begin{aligned}\hat{1}_{\{n\}} \quad = \quad & \sum_{\{\mu_i\}} \int \frac{\mathrm{d}^3 V}{(2\pi)^3 V_0} \left(\prod_{i=1}^{n-1} \frac{\mathrm{d}^3 k_i}{(2\pi)^3 2k_i^0} \right) \frac{\left(\sum_{i=1}^{n} k_i^0\right)^3}{2k_n^0} \\ & \times |V;\{\boldsymbol{k}_i,\mu_i\}\rangle\langle V;\{\boldsymbol{k}_i,\mu_i\}| .\end{aligned} \tag{2.77}$$

The corresponding orthogonality relation reads:

$$\begin{aligned}&\langle V';\{\boldsymbol{k}_i',\mu_i'\}|\,V;\{\boldsymbol{k}_i,\mu_i\}\rangle \\ &\quad = V_0\,\delta^3(\boldsymbol{V}'-\boldsymbol{V})\,\frac{(2\pi)^3 2k_n^0}{\left(\sum_{i=1}^{n} k_i^0\right)^3} \left(\prod_{i=1}^{n-1} (2\pi)^3 2k_i^0 \delta^3(\boldsymbol{k}_i'-\boldsymbol{k}_i) \right) \left(\prod_{i=1}^{n} \delta_{\mu_i'\mu_i} \right) .\end{aligned} \tag{2.78}$$

A derivation of these relations can be found in Ref. [Kra01]. The completeness and orthogonality relations, Eqs. (2.77) and (2.78), have to be modified for each occurring photon according to the replacements $\sum_{\mu_\gamma} \to \sum_{\mu_\gamma}(-\mathrm{g}^{\mu_\gamma\mu_\gamma})$ and $\delta_{\mu_\gamma\mu_\gamma'} \to (-\mathrm{g}^{\mu_\gamma\mu_\gamma'})$.

2.6.3 Clebsch-Gordan Coefficients

In the present work we restrict our considerations to systems consisting of $n = 3$ and $n = 4$ particles among which two particles (1 and 2) are coupled together forming a composite subsystem (12). The free two-body subsystem (12) is the subject of this section in which we proceed along the lines of Refs. [Pol09,KP91]. Since we will work in the velocity-state representation for 3 and 4 particles we adopt the notation (2.69) for the momenta and spins of the particles 1 and 2. It should be noted that $\boldsymbol{k}_1$ and $\boldsymbol{k}_2$ can take any value if they denote the momenta of particles 1 and 2 in the center of mass of the 3- or 4-particle system.

The aim of this section is to construct appropriate Clebsch-Gordan coefficients of the Poincaré group which define a two-particle basis on which $\hat{U}_{12}\left(\underline{\Lambda}, \underline{a}\right)$ acts irreducibly. This is equivalent to expressing tensor products of single-particle eigenstates in terms of linear combinations of two-particle eigenstates of the total four momentum such that this eigenstate at rest transforms with a $(2j + 1)$-dimensional irreducible representation of the SU(2) with respect to rotations [Pol09]:

$$\hat{U}_{12}\left(\underline{R}\right)|(m_{12}, j); \mathbf{0}, \mu_j\rangle = \sum_{\mu'_j} |(m_{12}, j); \mathbf{0}, \mu'_j\rangle D^j_{\mu'_j \mu_j}\left(\underline{R}\right) . \tag{2.79}$$

Here m_{12} is the free invariant mass of the (12)-subsystem given by

$$m_{12} = \sqrt{k^\mu_{12} k_{12\mu}} \quad \text{with} \quad k^\mu_{12} := k^\mu_1 + k^\mu_2 . \tag{2.80}$$

With the free velocity of the (12)-subsystem

$$w_{12} := \frac{k_{12}}{m_{12}} \tag{2.81}$$

we can define the relative (internal) momentum $\tilde{\boldsymbol{k}}$ of the the (12)-subsystem:[13]

$$\tilde{k}_i := B_{\mathrm{c}}^{-1}(\boldsymbol{w}_{12}) k_i \quad \text{with} \quad i = 1, 2 \quad \Rightarrow \quad \tilde{\boldsymbol{k}}_1 = -\tilde{\boldsymbol{k}}_2 =: \tilde{\boldsymbol{k}} . \tag{2.82}$$

In this representation the non-interacting mass operator $\hat{m}_{12}$ has the form

$$\hat{m}_{12} = \sqrt{m_1^2 + \hat{\tilde{\boldsymbol{k}}}^2} + \sqrt{m_2^2 + \hat{\tilde{\boldsymbol{k}}}^2} . \tag{2.83}$$

The velocities of the individual particles in the center-of-momentum frame of the (12)-subsystem then read

$$\tilde{w}_i := \frac{\tilde{k}_i}{m_i} \quad \text{with} \quad i = 1, 2 . \tag{2.84}$$

The two-particle state associated with the system at rest is obtained by applying a canonical boost $\hat{U}_{12}^{-1}[B_{\mathrm{c}}(\boldsymbol{w}_{12})]$ on the state $|\boldsymbol{k}_1, \mu_1; \boldsymbol{k}_2, \mu_2\rangle$ and multiplying the Wigner-D functions to the other side with the help of Eq. (C.7):

$$\begin{aligned} &|\tilde{\boldsymbol{k}}, \tilde{\mu}_1; -\tilde{\boldsymbol{k}}, \tilde{\mu}_2\rangle \\ &\quad = \sum_{\mu_1 \mu_2} \hat{U}_{12}^{-1}[B_{\mathrm{c}}(\boldsymbol{w}_{12})] |\boldsymbol{k}_1, \mu_1; \boldsymbol{k}_2, \mu_2\rangle \\ &\quad\quad \times D^{j_1}_{\mu_1 \tilde{\mu}_1}\left[\underline{R}_{\mathrm{W_c}}\left(\tilde{w}_1, B_{\mathrm{c}}(\boldsymbol{w}_{12})\right)\right] D^{j_2}_{\mu_2 \tilde{\mu}_2}\left[\underline{R}_{\mathrm{W_c}}\left(\tilde{w}_2, B_{\mathrm{c}}(\boldsymbol{w}_{12})\right)\right] . \end{aligned} \tag{2.85}$$

---

[13] Quantities with a 'tilde' always refer to the center-of-momentum frame of the (12)-subsystem.

This rest eigenstate of the four-momentum transforms under a rotation in the same way as rest eigenstates do in non-relativistic quantum mechanics:

$$\hat{U}_{12}(\underline{R})|\tilde{\boldsymbol{k}},\tilde{\mu}_1;-\tilde{\boldsymbol{k}},\tilde{\mu}_2\rangle = \sum_{\tilde{\mu}_1'\tilde{\mu}_2'} |\boldsymbol{R}\tilde{k},\tilde{\mu}_1';-\boldsymbol{R}\tilde{k},\tilde{\mu}_2'\rangle D^{j_1}_{\tilde{\mu}_1'\tilde{\mu}_1}\left[\underline{R}\right] D^{j_2}_{\tilde{\mu}_2'\tilde{\mu}_2}\left[\underline{R}\right] . \tag{2.86}$$

In the derivation of Eq. (2.86) we have exploited the special properties of canonical Wigner rotations, cf. Eq. (2.44). Eq. (2.86) reveals the benefit of using canonical boosts that permits to combine spins and angular momenta in the usual non-relativistic manner. We can couple the spins j_1 and j_2 of the particles 1 and 2 to the total spin s and the total spin and orbital angular momentum l to the total angular momentum j by using standard SU(2) Clebsch-Gordan coefficients $C^{s\mu_s}_{j_1\tilde{\mu}_1 j_2\tilde{\mu}_2} := \langle j_1,\tilde{\mu}_1; j_2,\tilde{\mu}_2|s,\mu_s\rangle$ and $C^{j\mu_j}_{s\mu_s l\mu_l} := \langle l,\mu_l; s,\mu_s|j,\mu_j\rangle$. Keeping this in mind we introduce

$$|\mathbf{0};\tilde{k};(l,s),j,\mu_j\rangle := \sum_{\tilde{\mu}_1\tilde{\mu}_2\mu_l\mu_s}\int_\Omega \mathrm{d}\Omega(\hat{\tilde{\boldsymbol{k}}})Y_{l\mu_l}(\hat{\tilde{\boldsymbol{k}}})|\tilde{\boldsymbol{k}},\tilde{\mu}_1;-\tilde{\boldsymbol{k}},\tilde{\mu}_2\rangle C^{s\mu_s}_{j_1\tilde{\mu}_1 j_2\tilde{\mu}_2} C^{j\mu_j}_{s\mu_s l\mu_l} \tag{2.87}$$

with $\tilde{k} := |\tilde{\boldsymbol{k}}|$. $\hat{\tilde{\boldsymbol{k}}} := \tilde{\boldsymbol{k}}/\tilde{k}$ and $\mathrm{d}\Omega(\hat{\tilde{\boldsymbol{k}}})$ being the two-dimensional surface element for the angular integration.[14] Here we have eliminated the angles in $\hat{\tilde{\boldsymbol{k}}}$ in favor of discrete quantum numbers using the usual spherical harmonics $Y_{l\mu_l}(\hat{\boldsymbol{k}}) := \langle\hat{\boldsymbol{k}}|l,\mu_l\rangle$. The quantum numbers s and l corresponding to total spin and orbital angular momentum label degeneracies. The spherical harmonics $Y_{l\mu_l}(\hat{\boldsymbol{k}})$ and the Clebsch-Gordan coefficients $C^{j\mu_j}_{l\mu_l s\mu_s}$ satisfy the orthogonality relations

$$\int_\Omega \mathrm{d}\Omega(\hat{\tilde{\boldsymbol{k}}}')Y^*_{l'\mu_l'}(\hat{\tilde{\boldsymbol{k}}}')Y_{l\mu_l}(\hat{\tilde{\boldsymbol{k}}}') = \delta_{ll'}\delta_{\mu_l\mu_l'} \tag{2.88}$$

and [VMK88]

$$\sum_{\mu_l\mu_s} C^{j'\mu_j'}_{l\mu_l s\mu_s} C^{j\mu_j}_{l\mu_l s\mu_s} = \delta_{jj'}\delta_{\mu_j\mu_j'} , \tag{2.89}$$

respectively. The rest eigenstate of Eq. (2.87) has the desired transformation properties under rotations as given in Eq. (2.79). Applying a canonical boost $\hat{U}_{12}[\underline{B}_\mathrm{c}(\boldsymbol{w}_{12})]$ on this state gives an irreducible representation:

$$\begin{aligned}
&|\boldsymbol{k}_{12};\tilde{k};(l,s),j,\mu_j\rangle \\
&\quad = \hat{U}_{12}[\underline{B}_\mathrm{c}(\boldsymbol{w}_{12})]|\mathbf{0};\tilde{k};(l,s),j,\mu_j\rangle \\
&\quad = \sum_{\tilde{\mu}_1\tilde{\mu}_2\mu_l\mu_s}\int_\Omega \mathrm{d}\Omega(\hat{\tilde{\boldsymbol{k}}})Y_{l\mu_l}(\hat{\tilde{\boldsymbol{k}}})|\boldsymbol{k}_1,\mu_1;\boldsymbol{k}_2,\mu_2\rangle C^{s\mu_s}_{j_1\tilde{\mu}_1 j_2\tilde{\mu}_2} C^{j\mu_j}_{l\mu_l s\mu_s} \\
&\qquad \times D^{j_1}_{\mu_1\tilde{\mu}_1}\left[\underline{R}_{\mathrm{W_c}}\left(\tilde{w}_1, B_\mathrm{c}(\boldsymbol{w}_{12})\right)\right] D^{j_2}_{\mu_2\tilde{\mu}_2}\left[\underline{R}_{\mathrm{W_c}}\left(\tilde{w}_2, B_\mathrm{c}(\boldsymbol{w}_{12})\right)\right] .
\end{aligned} \tag{2.90}$$

This state transforms irreducibly under the action of $\hat{U}_{12}(\underline{\Lambda},\underline{a})$, i.e. it has the transformation properties of a single-particle state, cf. Eq. (2.53). The states

---

[14] In this case the 'hat' denotes a *unit vector* and *not* an operator.

$|\boldsymbol{k}_{12}; \tilde{k}; (l,s), j, \mu_j\rangle$ defined by Eq. (2.90) are simultaneous eigenstates of the operators $\hat{m}_{12}$, $\hat{\boldsymbol{j}}_{\mathrm{c}}^2$, $\hat{j}_{\mathrm{c}}^3$ and $\hat{\boldsymbol{k}}_{12}$. These operators together with the canonically conjugate operators of $\hat{\boldsymbol{k}}_{12}$ and $\hat{j}_{\mathrm{c}}^3$ commute with $\hat{m}_{12}$ [Pol09].

Finally we write down the Clebsch-Gordan coefficients which are determined from Eq. (2.90) [KP91, Pol09]:

$$\begin{aligned}
&\langle \boldsymbol{k}_{12}; \tilde{k}; (l,s), j, \mu_j | \boldsymbol{k}_1, \mu_1; \boldsymbol{k}_2, \mu_2 \rangle \\
&= (2\pi)^6 \int_\Omega \mathrm{d}\Omega(\hat{\tilde{\boldsymbol{k}}}) 2k_1^0 \delta^3(\boldsymbol{k}_1 - \boldsymbol{B}_{\mathrm{c}}(\boldsymbol{w}_{12})\tilde{k}_1) 2k_2^0 \delta^3(\boldsymbol{k}_2 - \boldsymbol{B}_{\mathrm{c}}(\boldsymbol{w}_{12})\tilde{k}_2) Y^*_{l\mu_l}(\hat{\tilde{\boldsymbol{k}}}) \\
&\quad \times C^{s\mu_s}_{j_1\tilde{\mu}_1 j_2\tilde{\mu}_2} C^{j\mu_j}_{l\mu_l s\mu_s} D^{j_1}_{\tilde{\mu}_1\mu_1}[\underline{R}^{-1}_{\mathrm{W_c}}(\tilde{w}_1, B_{\mathrm{c}}(\boldsymbol{w}_{12}))] D^{j_2}_{\tilde{\mu}_2\mu_2}[\underline{R}^{-1}_{\mathrm{W_c}}(\tilde{w}_2, B_{\mathrm{c}}(\boldsymbol{w}_{12}))] \\
&= (2\pi)^6 \int_\Omega \mathrm{d}\Omega(\hat{\tilde{\boldsymbol{k}}}) 2k_{12}^0 \delta^3(\boldsymbol{k}_{12} - \boldsymbol{k}_1 - \boldsymbol{k}_2) \frac{2\tilde{k}_1^0 2\tilde{k}_1^0}{2m_{12}} \delta^3(\tilde{\boldsymbol{k}} - \boldsymbol{B}_{\mathrm{c}}^{-1}(\boldsymbol{w}_{12})k_1) Y^*_{l\mu_l}(\hat{\tilde{\boldsymbol{k}}}) \\
&\quad \times C^{s\mu_s}_{j_1\tilde{\mu}_1 j_2\tilde{\mu}_2} C^{j\mu_j}_{l\mu_l s\mu_s} D^{j_1}_{\tilde{\mu}_1\mu_1}[\underline{R}^{-1}_{\mathrm{W_c}}(\tilde{w}_1, B_{\mathrm{c}}(\boldsymbol{w}_{12}))] D^{j_2}_{\tilde{\mu}_2\mu_2}[\underline{R}^{-1}_{\mathrm{W_c}}(\tilde{w}_2, B_{\mathrm{c}}(\boldsymbol{w}_{12}))] \,.
\end{aligned} \tag{2.91}$$

Here we have used the Jacobian determinant $\left|\frac{\partial(\boldsymbol{k}_{12}, \tilde{\boldsymbol{k}})}{\partial(\boldsymbol{k}_1, \boldsymbol{k}_2)}\right| = \frac{k_{12}^0 \tilde{k}_1^0 \tilde{k}_2^0}{m_{12} k_1^0 k_2^0}$ in order to account for the change of variables in the delta functions. This Clebsch-Gordan coefficient in Eq. (2.91) corresponds to the coupling of 2 particles with canonical spin to a superposition of irreducible representations with canonical spin.

The state vectors in Eq. (2.90) are eigenstates of commuting self-adjoint operators. Their eigenvalues are the quantum numbers labeling the states in Eq. (2.90). The Clebsch-Gordan coefficient $C^{j\mu_j}_{l\mu_l s\mu_s}$ implies that the canonical spin operator $\hat{\boldsymbol{j}}_c$ of Eq. (2.43) is the sum of 2 other operators $\hat{\boldsymbol{l}}$ and $\hat{\boldsymbol{s}}$, i.e.

$$\hat{\boldsymbol{j}}_c = \hat{\boldsymbol{l}} + \hat{\boldsymbol{s}} \,, \tag{2.92}$$

whose eigenvalues are l and s, respectively. The other Clebsch-Gordan coefficient $C^{s\mu_s}_{j_1\tilde{\mu}_1 j_2\tilde{\mu}_2}$ implies that $\hat{\boldsymbol{s}}$ is a sum of 2 one-body spin operators, where each is rotated by a different Wigner rotation:

$$\hat{\boldsymbol{s}} = \boldsymbol{R}_{\mathrm{W_c}}\left[w_1, B_{\mathrm{c}}^{-1}(\boldsymbol{w}_{12})\right] \hat{j}_1 + \boldsymbol{R}_{\mathrm{W_c}}\left[w_2, B_{\mathrm{c}}^{-1}(\boldsymbol{w}_{12})\right] \hat{j}_2 \,. \tag{2.93}$$

Eq. (2.92) can be considered as defining equation for the operator $\hat{\boldsymbol{l}}$ with $\hat{\boldsymbol{j}}_c$ and $\hat{\boldsymbol{s}}$ defined by Eqs. (2.43) and (2.93), respectively [KP91].

Chapter 3

Dynamical Representations

In the previous section we were dealing with a free many-body theory. The aim of this chapter, in which we proceed partly along the lines of Refs. [KP91, Pol09, Kra01, KSK03, BKS11b], is to construct a relativistically invariant quantum mechanical model with interactions.

3.1 Introduction

The usual procedure of incorporating interactions into a free many-body theory is to add an interaction term to the free Hamiltonian $\hat{P}_n^0$. Simultaneously, the Poincaré commutation relations have to be retained in order to guarantee relativistic invariance. As we will see, the only consistent way of adding interactions to $\hat{P}_n^0$ and retaining the Poincaré algebra at the same time is to include interaction terms also in, at least, some of the 9 remaining Poincaré generators. Encountering some minimal sets of these interaction dependent generators will bring up the notion of Dirac's *relativistic forms of dynamics*. A Poincaré invariant prescription of building up an interacting quantum mechanical model from a free theory is the, so-called, *Bakamjian-Thomas construction*. In particular, this construction will be applied to instantaneous two-body interactions and to vertex interactions. The instantaneous interactions will be used to formulate a bound-state problem, whose solution provides a two-body wave function. The vertex interactions, which are motivated by a local quantum field theory, will allow us to set up a relativistic coupled-channel problem in the following chapter.

3.2 The Forms of Relativistic Dynamics

Wigner's fundamental theorem of Sec. 2.1 phrases the formal problem of constructing a relativistically invariant quantum theory. This amounts to finding a representation of the Poincaré generators in terms of self-adjoint operators that act on the multi-particle Hilbert space of Sec. 2.6 and satisfy the Poincaré algebra, Eqs. (2.10)-(2.12). For a many-body theory without interactions this is easily achieved. The multi-particle generators of Eq. (2.64), being tensor products of the one-body generators, trivially satisfy the Poincaré algebra. To set up an *interacting* quantum mechanical model is, however, a non-trivial task.

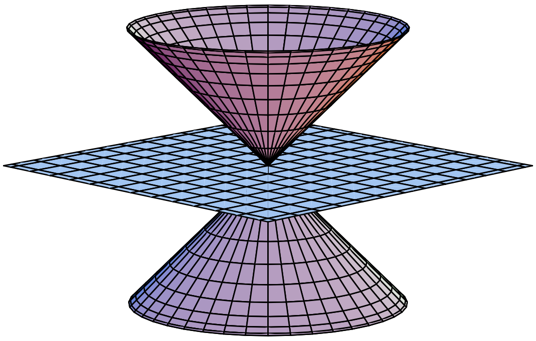

Figure 3.1: The space-like hypersurface of Minkowski-space $x^0 = 0$, which is invariant under the instant-form kinematic group of spatial translations and rotations. Indicated is also the light cone.

The complication can be seen most easily by taking a closer look at a particular commutation relation, namely Eq. (2.11),

$$[\hat{P}^j, \hat{K}^k] = \mathrm{i}\,\delta_{jk}\,\hat{P}^0\,, \tag{3.1}$$

between the generators for space translations $\hat{P}^j$ and the boost generators $\hat{K}^k$. This commutation relation already indicates that interaction terms must appear in more than just one of the Poincaré generators: if interaction terms are included in the Hamiltonian $\hat{P}^0$, which is the natural way of doing, i.e. $\hat{P}^0 = \hat{P}^0_n + \hat{P}^0_{\mathrm{int}}$, then $\hat{K}^k$ or $\hat{P}^j$ (or both) must be interaction dependent too. A particular *form* of relativistic dynamics is then characterized by the minimal set of Poincaré generators that have to contain interactions. In Dirac's seminal paper [Dir49] on the forms of classical relativistic dynamics the interaction dependent (*dynamical*) Poincaré generators are called *Hamiltonians.* The remaining interaction free generators are called *kinematic* and they generate the, so-called, *kinematic group.* The kinematic group of a form leaves a particular space-like (or light-like) hypersurface of Minkowski space invariant. In this way there is a hypersurface associated with each form of relativistic dynamics.

The most prominent forms are the *instant form*, the *front form* and the *point form* (for a thorough discussion on the relativistic forms of dynamics we refer to Refs. [Dir49,KP91,Kra01]). The instant form is the standard form characterized by the set of dynamical generators given by $\{\hat{P}^0, \hat{K}^1, \hat{K}^2, \hat{K}^3\}$. Its kinematic group consists of spatial translations and rotations leaving the hypersurface of the *instant* $x^0 = 0$ invariant. This hypersurface is depicted in Fig. 3.1. In the case of the front form the hypersurface left invariant under the action of the associated kinematic group is the light *front* $x^0 + x^3 = 0$, which is illustrated in Fig. 3.2. A special feature about the front form is the fact that it has the largest kinematic group containing 7 generators. The remaining 3 dynamical generators are given by $\{\hat{P}^0 - \hat{P}^3, \hat{K}^1 - \hat{J}^2, \hat{K}^2 + \hat{J}^1\}$. Among the three forms the point

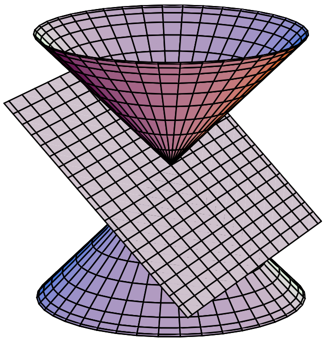

Figure 3.2: The light-like hypersurface $x^0 + x^3 = 0$ associated with the front form (together with the light cone).

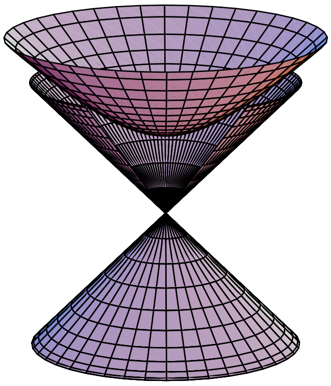

Figure 3.3: The forward hyperboloid $x^\mu x_\mu = \tau^2$, which is invariant under the Lorentz group, the kinematic group of the point form (together with the light cone).

form is the least known and, although it has definite virtues, the least utilized. The kinematic group of the point form is the Lorentz group, which leaves the hyperboloid $x^\mu x_\mu = \tau^2$ (plotted in Fig. 3.3) and in particular the *point* $x^\mu = 0$ invariant. The point-form set of Hamiltonians is given by $\{\hat{P}^0, \hat{P}^1, \hat{P}^2, \hat{P}^3\}$, which provides a clean separation of Poincaré generators that are interaction dependent from those that are interaction free. The former are components of the four-vector $\hat{P}^\mu$ whereas the latter can be combined into the antisymmetric Lorentz tensor $\hat{M}^{\mu\nu}$, which has been already introduced in Sec. 2.2. This permits to express equations in point form in a manifestly Lorentz covariant form and makes for simple behavior under Lorentz transformations. The conditions for Poincaré invariance can, e.g., be phrased in terms of the *point-form equations*

$$[\hat{P}^\mu, \hat{P}^\nu] = 0 \quad \text{and} \quad \hat{U}(\underline{\Lambda})\, \hat{P}^\mu\, \hat{U}^\dagger(\underline{\Lambda}) = (\Lambda^{-1})^\mu{}_\nu \hat{P}^\nu \,. \tag{3.2}$$

Here the Lorentz part of the Poincaré commutation relations has been integrated out, which is possible due to the kinematic nature of the rotation and boost generators.

3.3 The Bakamjian-Thomas Construction

By looking at the commutation relations involving the dynamical Poincaré generators it is evident that the interaction terms are, in general, subject to non-linear constraints. It has been already realized by Dirac in Ref. [Dir49] that such conditions imposed by the Poincaré algebra are in general not easily fulfilled. This makes the problem of constructing a Poincaré-invariant few-body quantum theory quite intricate. A particular solution to the problem of finding a consistent set of the 10 Poincaré generators for an interacting quantum mechanical system with finitely many degrees of freedom is the, so-called, *Bakamjian-Thomas construction* proposed by Bakamjian and Thomas in Ref. [BT53]. This construction is summarized as follows (for a detailed discussion we refer to Refs. [KP91, Kra01]): One starts with the non-interacting Poincaré generators, Eq. (2.64), which satisfy the Poincaré algebra trivially. From these generators one constructs a particular set of auxiliary operators which depends on the form of dynamics. The Poincaré algebra requires certain commutation relations between these auxiliary operators. One of these operators is always the free mass operator $\hat{M}_n$. In the next step an interaction term $\hat{M}_{\text{int}}$ is added only to this mass operator to obtain an interacting mass operator

$$\hat{M} = \hat{M}_n + \hat{M}_{\text{int}} \,. \tag{3.3}$$

This interaction has to commute with all auxiliary operators such that the commutation relations between the auxiliary operators remain satisfied. This imposes linear constraints on the interaction terms which are, in general, easier to satisfy than the non-linear constraints imposed by the Poincaré algebra. In the final step the interacting Poincaré generators are (re-)constructed by simply replacing the free mass operator with the interacting mass operator in the expressions that define the generators in terms of the auxiliary operators. The commutation relations between the auxiliary operators imply that the Poincaré algebra is satisfied. This ensures relativistic invariance of the interacting quantum mechanical model resulting from this construction.

Instant Form

It is clear that the set of auxiliary operators depends on the set of dynamical generators and is therefore different for each form of relativistic dynamics. In the instant form the auxiliary operators are given by $\hat{M}_n, \hat{\boldsymbol{P}}_n, \hat{\boldsymbol{X}}_{\text{c}}, \hat{\boldsymbol{J}}_{\text{c}}^2, \hat{J}_{\text{c}}^3$ and the operator canonically conjugate to $\hat{J}_{\text{c}}^3$. Equivalently, one can take the set $\{\hat{M}_n, \hat{\boldsymbol{P}}_n, \hat{\boldsymbol{J}}_{\text{c}}, \hat{\boldsymbol{X}}_{\text{c}}\}$. In this case the only generators that are mass dependent and therefore become interaction dependent are the Hamiltonian $\hat{P}^0$ and the boost generators $\hat{\boldsymbol{K}}$, cf. Eqs. (2.33) and (2.48). The instant-form conditions on the interaction term ensuring Poincaré invariance read

$$[\hat{M}_{\text{int}}, \hat{\boldsymbol{P}}_n] = [\hat{M}_{\text{int}}, \hat{\boldsymbol{J}}_{\text{c}}] = [\hat{M}_{\text{int}}, \hat{\boldsymbol{X}}_{\text{c}}] = 0\,. \tag{3.4}$$

Point Form

If the Bakamjian-Thomas construction is carried out in the point form the set of auxiliary operators is given by $\{\hat{M}_n, \hat{\boldsymbol{V}}, \hat{M}_n\hat{\boldsymbol{X}}_{\text{c}}, \hat{\boldsymbol{J}}_{\text{c}}\}$ or equivalently (cf. Eqs. (2.47) and (2.48)) by $\{\hat{M}_n, \hat{\boldsymbol{V}}, \hat{\boldsymbol{K}}_n, \hat{\boldsymbol{J}}_n\}$. Then the resulting interacting four-momentum operator $\hat{P}^\mu$ is seen to separate into an interacting mass operator $\hat{M}$ and the free four-velocity operator $\hat{V}^\mu$,

$$\hat{P}^\mu = \hat{P}^\mu_n + \hat{P}^\mu_{\text{int}} = \left(\hat{M}_n + \hat{M}_{\text{int}}\right)\hat{V}^\mu\,. \tag{3.5}$$

The point-form equations (3.2) imply that the interacting part of the mass operator $\hat{M}_{\text{int}}$ must be a Lorentz scalar that has to commute with the free velocity operator, i.e.

$$[\hat{M}_{\text{int}}, \hat{V}^\mu] = [\hat{M}_{\text{int}}, \hat{M}^{\mu\nu}_n] = 0\,. \tag{3.6}$$

Equivalently, these point-form conditions on the Bakamjian-Thomas type mass operator $\hat{M}_{\text{int}}$ can be rewritten in terms of the operators $\hat{\boldsymbol{X}}_{\text{c}}$ and $\hat{\boldsymbol{J}}_{\text{c}}$ as

$$[\hat{M}_{\text{int}}, \hat{V}^\mu] = [\hat{M}_{\text{int}}, \hat{\boldsymbol{X}}_{\text{c}}] = [\hat{M}_{\text{int}}, \hat{\boldsymbol{J}}_{\text{c}}] = 0\,. \tag{3.7}$$

Remarks

One benefit of the Bakamjian-Thomas approach is that the operator for the total spin $\hat{\boldsymbol{J}}_{\text{g}}$ of the interacting system is not affected by interactions.

Furthermore, the Bakamjian-Thomas framework allows one to construct Poincaré invariant models with instantaneous interactions, i.e. action at a distance. What one loses with instantaneous interactions as compared to a local quantum field theory is, however, *microscopic locality.* Microscopic locality, which is sometimes also called *Einstein causality* or *microcausality*, roughly means that 2 observables commute if they are associated with 2 different regions of space-time that are separated by an arbitrarily small space-like distance [SW00, KP91]. It is possible to find infinitely many such independent observables for every finite space-time volume which implies that microscopic locality requires an infinite number of degrees of freedom. Therefore, in a relativistic quantum theory with a *finite* number of degrees of freedom this property of microcausality is replaced by the weaker condition of *macroscopic* locality, which is sometimes called *cluster separability* or *macrocausality* [Fol61]. For a definition of macrocausality one simply replaces 'arbitrarily small' by 'sufficiently large' in the definition of microcausality. In other words, macrocausality means that disjunct subsystems of a quantum mechanical system should behave independently from each other, if they are separated by sufficiently large space-like distances. It turns out that it is the condition of macrocausality (and not microcausality) that can be tested by experiments [KP91].

As we will see, however, already for systems consisting of more than 2 particles, the Bakamjian-Thomas framework will violate not only microcausality, but also macrocausality.

3.4 Two-Body Interactions

Our aim is to find a two-body interaction defined on a three-particle Hilbert space within a point-form Bakamjian-Thomas framework. This means that we have conservation of the overall four-velocity of the three-particle system, i.e. the incoming and outgoing four velocities are equal. At the same time, the incoming and outgoing three-momenta of the non-interacting particles satisfy spectator conditions. These 2 requirements imply that the four-velocity of the interacting two-particle subsystem cannot be conserved. Therefore, we cannot directly use the point-form Bakamjian-Thomas construction on the two-particle Hilbert space to define the two-body interaction on the three-body Hilbert space. One way to satisfy the above requirements is to define the two-body interaction on the two-particle Hilbert space in a way that resembles the instant-form Bakamjian-Thomas framework and then imbed this two-body interaction consistent with the point-form Bakamjian-Thomas framework into the three-body Hilbert space.

3.4.1 Two-Body Mass Operator

It has been mentioned already that instantaneous interactions can be used within the Bakamjian-Thomas framework without losing Poincaré invariance. In this section we concentrate on the incorporation of instantaneous two-body interactions into a quantum mechanical model.

To this end we use an instant-form Bakamjian-Thomas construction formulated on a two-particle Hilbert space. In our rather brief discussion we follow closely the more detailed disquisitions of Refs. [Pol09, KP91]. In Sec. 2.6.3 we have derived a basis for free two-particle states given by $|\boldsymbol{k}_{12}; \tilde{k}; (l,s), j, \mu_j\rangle$ which transforms irreducibly under the non-interacting unitary representation $\hat{U}_{12}(\underline{\Lambda}, \underline{a})$. The free invariant mass operator $\hat{m}_{12}$ of the two-body system in this representation was given by Eq. (2.83). An interaction between particles 1 and 2 is introduced by adding an interaction operator $\hat{m}_{\text{int}}$ to the free mass operator according to Eq. (3.3) to obtain a total mass operator for the two-particle cluster C:

$$\hat{m}_{\text{C}} := \hat{m}_{12} + \hat{m}_{\text{int}} \,. \tag{3.8}$$

Poincaré invariance requires that the instant-form set of the auxiliary operators $\{\hat{m}_{\text{C}}, \hat{\boldsymbol{k}}_{12}, \hat{\boldsymbol{j}}_{\text{c}}, \hat{\boldsymbol{x}}_{\text{c}}\}$ satisfies the same commutation relations as $\{\hat{m}_{12}, \hat{\boldsymbol{k}}_{12}, \hat{\boldsymbol{j}}_{\text{c}}, \hat{\boldsymbol{x}}_{\text{c}}\}$ which implies the instant-form constraints Eq. (3.4) on $\hat{m}_{\text{int}}$:

$$\left[\hat{\boldsymbol{k}}_{12}, \hat{m}_{\text{int}}\right] = \left[\hat{\boldsymbol{j}}_{\text{c}}, \hat{m}_{\text{int}}\right] = \left[\hat{\boldsymbol{x}}_{\text{c}}, \hat{m}_{\text{int}}\right] = 0 \,. \tag{3.9}$$

From these conditions on $\hat{m}_{\text{int}}$ we infer that matrix elements of $\hat{m}_{\text{int}}$ in the non-interacting representation $|\boldsymbol{k}_{12}; \tilde{k}; l, s, j, \mu_j\rangle$ can be written in the form

$$\begin{aligned} &\langle \boldsymbol{k}'_{12}; \tilde{k}'; (l', s'), j', \mu'_j | \hat{m}_{\text{int}} | \boldsymbol{k}_{12}; \tilde{k}; (l,s), j, \mu_j \rangle \\ &\quad = \delta_{jj'} \delta_{\mu_j \mu'_j} (2\pi)^3 2k^0_{12} \delta^3\left(\boldsymbol{k}_{12} - \boldsymbol{k}'_{12}\right) \langle \tilde{k}'; l', s' || \hat{m}^j_{\text{int}} || \tilde{k}; l, s \rangle \,. \end{aligned} \tag{3.10}$$

Here the reduced kernel $\langle \tilde{k}'; l', s' || \hat{m}^j_{\text{int}} || \tilde{k}; l, s \rangle$ is independent of the total two-particle momentum $\boldsymbol{k}_{12}$ and the total spin projection μ_j. The eigenvalue problem for the mass operator $\hat{m}_{\mathrm{C}}$ is given by

$$\left(\sqrt{m_1^2+\hat{\tilde{\boldsymbol{k}}}^2}+\sqrt{m_2^2+\hat{\tilde{\boldsymbol{k}}}^2}+\hat{m}_{\mathrm{int}}\right)|\Psi_{\mathrm{C}}\rangle = m_{\mathrm{C}}|\Psi_{\mathrm{C}}\rangle\,. \tag{3.11}$$

In the present work we concentrate on the study of bound states.[1] Therefore, the eigenvalue equation (3.11) is considered to be a bound-state equation leading to a discrete spectrum of $\hat{m}_{\mathrm{C}}$. The eigenvalues of $\hat{m}_{\mathrm{C}}$ will be denoted by m_n where $n = 0, 1, 2, \ldots$ is the quantum number for radial excitations.

We have constructed $\hat{m}_{\mathrm{C}}$ in such a way that it satisfies the same commutation relations as $\hat{m}_{12}$, i.e. it commutes with the remaining (free) auxiliary operators $\hat{\boldsymbol{j}}_{\mathrm{c}}^2$, $\hat{j}_{\mathrm{c}}^3$, $\hat{\boldsymbol{k}}_{12}$, $\hat{\boldsymbol{x}}_{\mathrm{c}}$ and the operator canonically conjugate to $\hat{j}_{\mathrm{c}}^3$ [Pol09]. Thus, there exist simultaneous eigenstates of $\hat{m}_{\mathrm{C}}$, $\hat{\boldsymbol{j}}_{\mathrm{c}}^2$, $\hat{j}_{\mathrm{c}}^3$ and $\hat{\boldsymbol{k}}_{12}$ denoted by $|\boldsymbol{k}_{12}; m_n, j, \mu_j\rangle \equiv |\boldsymbol{k}_{12}; n, j, \mu_j\rangle$. These states transform irreducibly under the action of $\hat{U}_{\mathrm{C}}\left(\underline{\Lambda}, \underline{a}\right)$ and thus define a dynamical representation of the Poincaré group. It is simply obtained by replacing all eigenvalues m_{12} by m_n in the non-interacting representation defined by the action of $\hat{U}_{12}\left(\underline{\Lambda}, \underline{a}\right)$ on the non-interacting states $|\boldsymbol{k}_{12}; \tilde{k}, (l, s), j, \mu_j\rangle$ [KP91]. Then, the four-momentum of the interacting two-particle cluster is given by

$$k_{\mathrm{C}} := \begin{pmatrix} k_{\mathrm{C}}^0 \\ \boldsymbol{k}_{12} \end{pmatrix} \quad \text{with} \quad k_{\mathrm{C}}^0 := \sqrt{\boldsymbol{k}_{12}^2 + m_{\mathrm{C}}^2}\,. \tag{3.12}$$

Bound-State Wave Function

Solving the bound-state problem Eq. (3.11) leads to mass eigenfunctions of the form

$$\begin{aligned}&\langle \boldsymbol{k}_{12}'; \tilde{k}'; (l', s'), j', \mu_j' | \boldsymbol{k}_{12}; n, j, \mu_j\rangle \\ &\quad = \bar{N}_2 \delta_{jj'} \delta_{\mu_j \mu_j'} \delta^3\left(\boldsymbol{k}_{12} - \boldsymbol{k}_{12}'\right) u^j_{nl's'}(\tilde{k}')\end{aligned} \tag{3.13}$$

where $\bar{N}_2$ is a normalization constant. From Eq. (3.13), using Eqs. (2.90) and (2.91) together with the relations Eqs. (C.5), (2.88) and (2.89), we obtain a representation of the eigenfunctions in terms of constituents' degrees of freedom

$$\langle \boldsymbol{k}_1', \mu_1'; \boldsymbol{k}_2', \mu_2' | \boldsymbol{k}_{12}; n, j, \mu_j\rangle = \tilde{N}_2 \delta^3\left(\boldsymbol{k}_{12} - \boldsymbol{k}_1' - \boldsymbol{k}_2'\right) \Psi_{nj\mu_j\mu_1'\mu_2'}(\tilde{\boldsymbol{k}}')\,, \tag{3.14}$$

where $\tilde{N}_2$ is a normalization constant and with the wave function defined by

$$\begin{aligned}&\Psi_{nj\mu_j\mu_1'\mu_2'}(\tilde{\boldsymbol{k}}') \\ &\quad := \sum_{l s \mu_l \mu_s \tilde{\mu}_1 \tilde{\mu}_2} Y_{l\mu_l}(\hat{\tilde{\boldsymbol{k}}}') C^{s\mu_s}_{j_1\tilde{\mu}_1 j_2 \tilde{\mu}_2} C^{j\mu_j}_{l\mu_l s\mu_s} u^j_{nls}(\tilde{k}') \\ &\qquad \times D^{j_1}_{\mu_1'\tilde{\mu}_1}\left[\underline{R}_{\mathrm{W_c}}\left(\tilde{w}_1', B_{\mathrm{c}}(\boldsymbol{w}_{12}')\right)\right] D^{j_2}_{\mu_2'\tilde{\mu}_2}\left[\underline{R}_{\mathrm{W_c}}\left(\tilde{w}_2', B_{\mathrm{c}}(\boldsymbol{w}_{12}')\right)\right]\,.\end{aligned} \tag{3.15}$$

We normalize this wave function to unity:

$$\int \mathrm{d}^3\tilde{k}' \sum_{\mu_1'\mu_2'} \Psi^*_{nj\mu_j\mu_1'\mu_2'}(\tilde{\boldsymbol{k}}') \Psi_{n'j'\mu_j'\mu_1'\mu_2'}(\tilde{\boldsymbol{k}}') = \delta_{nn'}\delta_{jj'}\delta_{\mu_j\mu_j'}\,. \tag{3.16}$$

---

[1] From now on we will also refer to the particles 1 and 2 as the constituents c_1 and c_2 of the bound state C.

3.4.2 Embedding into a Three-Particle Hilbert Space

In the next step we embed the two-body interaction defined by Eq. (3.10) into a three-body Hilbert space of a system consisting of the two interacting particles 1 and 2 plus an additional spectator particle denoted by e.[2] To this end we pursue a similar strategy as presented in Ref. [KP91].

In the velocity-state basis of Sec. 2.6.2 the free three-particle system is represented by the state vector $|V;\boldsymbol{k}_1,\mu_1;\boldsymbol{k}_2,\mu_2;(\boldsymbol{k}_\mathrm{e}),\mu_\mathrm{e}\rangle$. The momentum in brackets is redundant since the momenta occurring here are subject to center-of-mass constraints, cf. Eq. (2.68). With the help of the Clebsch-Gordan coefficients for the Poincaré group, Eq. (2.91), we can perform a basis change to $|V;\boldsymbol{k}_{12},\tilde{k},(l,s),j,\mu_j;(\boldsymbol{k}_\mathrm{e}),\mu_\mathrm{e}\rangle$. In this basis we define the interaction on the three-body Hilbert space by simply including another Dirac delta function and 2 other Kronecker deltas in the definition of the two-body interaction in Eq. (3.10). The additional delta function corresponds to overall-velocity conservation and is given by $V^0\delta^3(\boldsymbol{V}-\boldsymbol{V}')$. The 2 additional Kronecker deltas $\delta_{JJ'}$ and $\delta_{M_J M_J'}$ correspond to the total angular momentum of the three-particle system $|\boldsymbol{J}_\mathrm{c}^{(\prime)}| = |\boldsymbol{j}_\mathrm{c}^{(\prime)} + \boldsymbol{j}_\mathrm{c,e}^{(\prime)}|$ and its projection into the 3-direction $M_J^{(\prime)} = \mu_j^{(\prime)} + \mu_\mathrm{e}^{(\prime)}$, respectively. Therefore, due to the Kronecker delta $\delta_{\mu_j\mu_j'}$ occurring in Eq. (3.10) (implying $\mu_j = \mu_j'$), we can replace $\delta_{M_J M_J'}$ by $\delta_{\mu_\mathrm{e}\mu_\mathrm{e}'}$. Furthermore, due to the center-of-mass kinematics for velocity states, we can use $\delta^3(\boldsymbol{k}_{12}-\boldsymbol{k}_{12}') = \delta^3(\boldsymbol{k}_\mathrm{e}-\boldsymbol{k}_\mathrm{e}')$. With these manipulations the definition of the two-body interaction on the three-body Hilbert space reads

$$\begin{aligned}&\langle V';\boldsymbol{k}_{12}',\tilde{k}',(l',s'),j',\mu_j';(\boldsymbol{k}_\mathrm{e}'),\mu_\mathrm{e}'|\hat{m}_\mathrm{int}|V;\boldsymbol{k}_{12},\tilde{k},(l,s),j,\mu_j;(\boldsymbol{k}_\mathrm{e}),\mu_\mathrm{e}\rangle\\ &\quad := NV^0\delta^3(\boldsymbol{V}-\boldsymbol{V}')\delta_{jj'}\delta_{\mu_j\mu_j'}\delta_{\mu_\mathrm{e}\mu_\mathrm{e}'}\delta^3(\boldsymbol{k}_\mathrm{e}-\boldsymbol{k}_\mathrm{e}')\langle\tilde{k}';l',s'||\hat{m}^j_\mathrm{int}||\tilde{k};l,s\rangle\,,\end{aligned} \tag{3.17}$$

where N is a normalization constant which is not fixed for the moment. The interaction $\hat{m}_\mathrm{int}$ satisfies the following commutation relations with the operators of the non-interacting system:

$$[\hat{m}_\mathrm{int},\hat{\boldsymbol{V}}] = [\hat{m}_\mathrm{int},\hat{\boldsymbol{J}}_\mathrm{c}] = [\hat{m}_\mathrm{int},\hat{\boldsymbol{X}}_\mathrm{c}] = 0\,, \tag{3.18}$$

$$[\hat{m}_\mathrm{int},\hat{\boldsymbol{k}}_\mathrm{e}] = [\hat{m}_\mathrm{int},\hat{\boldsymbol{j}}_\mathrm{c,e}] = 0\,. \tag{3.19}$$

The first commutation relations Eq. (3.18) are identical with the conditions of a point-form Bakamjian-Thomas construction (cf. Eq. (3.7)) which means that Eq. (3.17) defines a point-form Bakamjian-Thomas type mass operator. The commutation relations (3.19) follow from Eq. (3.9) and can be viewed as *spectator conditions* for the additional particle which has been assumed to be a non-interacting spectator. Note that Eqs. (3.18) and (3.19) imply that $[\hat{m}_\mathrm{int},\hat{\boldsymbol{j}}_\mathrm{c}] = 0$, which corresponds to the Kronecker deltas $\delta_{\mu_j\mu_j'}$ and $\delta_{jj'}$ in Eq. (3.17). Furthermore, $[\hat{m}_\mathrm{int},\hat{\boldsymbol{k}}_\mathrm{e}] = 0$ is equivalent to $[\hat{m}_\mathrm{int},\hat{\boldsymbol{k}}_{12}] = 0$ since $\hat{\boldsymbol{k}}_{12} = -\hat{\boldsymbol{k}}_\mathrm{e}$. Hence, the commutation relations on the two-body Hilbert-space, Eq. (3.9), remain valid. Eq. (3.17) reveals that in a velocity-state representation of a Bakamjian-Thomas type model the overall velocity of the system can always be factored out as a velocity-conserving delta function, leaving the part for the pure internal motion.

---

[2] 'e' will stand later for 'electron', not to be confused with the elementary charge. The distinction between them should, however, be clear from the context.

Four-Momentum Operator

The next objective is to find a representation of the four-momentum operator corresponding to the interaction of Eq. (3.17) on the three-body Hilbert space. To this end we define the interacting mass operator associated with the interacting pair and the spectator particle by

$$\hat{M}_{\mathrm{Ce}} := \sqrt{\hat{\boldsymbol{k}}_{\mathrm{e}}^2 + \hat{m}_{\mathrm{C}}^2} + \sqrt{\hat{\boldsymbol{k}}_{\mathrm{e}}^2 + m_{\mathrm{e}}^2}\,. \tag{3.20}$$

Then we can determine the two-body interaction on the three-body Hilbert space by subtracting the free mass operator $\hat{M}_{12\mathrm{e}}$ from Eq. (3.20):

$$\hat{M}_{\mathrm{int}} := \hat{M}_{\mathrm{Ce}} - \hat{M}_{12\mathrm{e}}\,. \tag{3.21}$$

This operator satisfies the same commutations relations as $\hat{m}_{\mathrm{int}}$, cf. Eqs. (3.18) and (3.19). Finally, the interacting four-momentum operator associated with $\hat{M}_{e\mathrm{C}}$ of Eq. (3.20) is easily obtained from Eq. (3.5):

$$\hat{P}^{\mu} = \hat{M}_{e\mathrm{C}} \hat{V}^{\mu}\,. \tag{3.22}$$

Bound-State Wave Function

Next we look at the matrix elements of free and *clustered*[3] velocity states $\langle V'; \boldsymbol{k}_1', \mu_1'; \boldsymbol{k}_2', \mu_2'; (\boldsymbol{k}_{\mathrm{e}}'), \mu_{\mathrm{e}}' | V; \boldsymbol{k}_{12}, n, j, \mu_j; (\boldsymbol{k}_{\mathrm{e}}), \mu_{\mathrm{e}} \rangle$ which define the two-body wave function on the three-body Hilbert space. As a consequence of Eq. (3.17) they have the general form [KSK03]

$$\begin{aligned}
&\langle V'; \boldsymbol{k}_1', \mu_1'; \boldsymbol{k}_2', \mu_2'; (\boldsymbol{k}_{\mathrm{e}}'), \mu_{\mathrm{e}}' | V; \boldsymbol{k}_{12}, n, j, \mu_j; (\boldsymbol{k}_{\mathrm{e}}), \mu_{\mathrm{e}} \rangle \\
&\quad = N_3 V^0 \delta^3(\boldsymbol{V} - \boldsymbol{V}') \delta_{\mu_{\mathrm{e}} \mu_{\mathrm{e}}'} \delta^3\left(\boldsymbol{k}_{\mathrm{e}} - \boldsymbol{k}_{\mathrm{e}}'\right) \Psi_{n j \mu_j \mu_1' \mu_2'}(\tilde{\boldsymbol{k}}')\,,
\end{aligned} \tag{3.23}$$

where we have used Eq. (3.14) together with the relation $\delta^3\left(\boldsymbol{k}_{12} - \boldsymbol{k}_1' - \boldsymbol{k}_2'\right) = \delta^3\left(\boldsymbol{k}_{\mathrm{e}} - \boldsymbol{k}_{\mathrm{e}}'\right)$. $\tilde{\boldsymbol{k}}'$ is the momentum of particle 1 in the center of momentum of the free (12)-subsystem (cf. Eq. (2.82)). The normalization factor N_3 occurring in Eq. (3.23) is fixed by the normalization of the states $|V; \boldsymbol{k}_{12}, n, j, \mu_j; (\boldsymbol{k}_{\mathrm{e}}), \mu_{\mathrm{e}}\rangle$, cf. Eq. (2.78), which reads

$$\begin{aligned}
&\langle V''; \boldsymbol{k}_{12}'', n'', j'', \mu_j''; (\boldsymbol{k}_{\mathrm{e}}''), \mu_{\mathrm{e}}'' | V; \boldsymbol{k}_{12}, n, j, \mu_j; (\boldsymbol{k}_{\mathrm{e}}), \mu_{\mathrm{e}} \rangle \\
&\quad = (2\pi)^6 V^0 \delta^3(\boldsymbol{V} - \boldsymbol{V}'') \tfrac{2k_{\mathrm{C}}^0 2k_{\mathrm{e}}^0}{(k_{\mathrm{C}}^0 + k_{\mathrm{e}}^0)^3} \delta^3(\boldsymbol{k}_{12} - \boldsymbol{k}_{12}'') \delta_{nn''} \delta_{jj''} \delta_{\mu_j \mu_j''} \delta_{\mu_{\mathrm{e}} \mu_{\mathrm{e}}''}\,.
\end{aligned} \tag{3.24}$$

N_3 is computed as follows: first we insert the three-particle velocity state unit $\hat{1}_{12\mathrm{e}}'$ of Eq. (2.77) into the bracket of the left-hand side of Eq. (3.24) and use the Jacobian

$$\frac{\mathrm{d}^3 k_1}{2k_1^0} \frac{\mathrm{d}^3 k_{\mathrm{e}}}{2k_{\mathrm{e}}^0} \frac{(k_1^0 + k_2^0 + k_{\mathrm{e}}^0)^3}{2k_2^0} = \frac{\mathrm{d}^3 k_{\mathrm{e}}}{2k_{\mathrm{e}}^0} \frac{\mathrm{d}^3 \tilde{k}}{2\tilde{k}_1^0} \frac{2(\tilde{k}_1^0 + \tilde{k}_2^0)}{\tilde{k}_2^0} \frac{(k_{12}^0 + k_{\mathrm{e}}^0)^3}{2k_{12}^0}\,. \tag{3.25}$$

---

[3] With *clustered velocity states* we mean velocity states which describe a n-particle system where particles 1 and 2 form a bound system.

After performing the $\boldsymbol{V}'$- and $\boldsymbol{k}'_\mathrm{e}$-integrations together with the sum over μ'_e the left-hand side of Eq. (3.24) becomes

$$
\begin{aligned}
&\langle V''; \boldsymbol{k}''_{12}; n''j'', \mu''_j; (\boldsymbol{k}''_\mathrm{e}), \mu''_\mathrm{e} | \hat{1}'_{12\mathrm{e}} | V; \boldsymbol{k}_{12}, n, j, \mu_j; (\boldsymbol{k}_\mathrm{e}), \mu_\mathrm{e}\rangle \\
&= \frac{1}{(2\pi)^9} V^0 \delta^3(\boldsymbol{V} - \boldsymbol{V}'') \delta^3(\boldsymbol{k}_\mathrm{e} - \boldsymbol{k}''_\mathrm{e}) \int \frac{\tilde{k}'^2 \mathrm{d}\tilde{k}'}{2\tilde{k}'^0_1} \frac{2(\tilde{k}'^0_1 + \tilde{k}'^0_2)}{2\tilde{k}'^0_2} \frac{(k'^0_{12} + k'^0_\mathrm{e})^3}{2k'^0_{12} 2k'^0_\mathrm{e}} N_3^2 \\
&\quad \times \int \mathrm{d}\Omega(\hat{\tilde{\boldsymbol{k}}}') \sum_{\mu'_1 \mu'_2} \Psi^*_{n''j''\mu''_j \mu'_1 \mu'_2}(\tilde{\boldsymbol{k}}') \Psi_{nj\mu_j \mu'_1 \mu'_2}(\tilde{\boldsymbol{k}}') \,. \qquad (3.26)
\end{aligned}
$$

With the normalization of the wave function, Eq. (3.16), and from comparison of the result with the right-hand side of Eq. (3.24), we finally infer that the normalization factor has the form

$$
N_3 = (2\pi)^{15/2} \sqrt{\frac{2\tilde{k}'^0_1 2\tilde{k}'^0_2}{2(\tilde{k}'^0_1 + \tilde{k}'^0_2)}} \sqrt{\frac{2k^0_\mathrm{C} 2k^0_\mathrm{e}}{(k^0_\mathrm{C} + k^0_\mathrm{e})^3}} \sqrt{\frac{2k'^0_{12} 2k'^0_\mathrm{e}}{(k'^0_{12} + k'^0_\mathrm{e})^3}} \,. \qquad (3.27)
$$

Transformation Properties

In this subsection we investigate the transformation properties of the wave function $\Psi_{nj\mu_j\mu'_1\mu'_2}(\tilde{\boldsymbol{k}})$ under Lorentz transformations. For simplicity, we restrict ourselves to a wave function with $l = 0$, which is often referred to as *s-wave.* In this case the Clebsch-Gordan coefficients and the spherical harmonics are simple expressions given by $C^{j\mu_j}_{00s\mu_s} = \delta_{sj}\delta_{\mu_s\mu_j}$ and $Y_{00}(\hat{\tilde{\boldsymbol{k}}}') = 1/\sqrt{4\pi}$. Then, from the normalization condition of the wave function, Eq. (3.16), using the property of the Wigner D-functions, Eq. (C.5), together with the orthogonality relations for the Clebsch-Gordan coefficients, Eq. (2.89), we find the following orthogonality relation for the radial wave function $u_{n0}(\tilde{k}) \equiv u^j_{n0j}(\tilde{k})$:

$$
\int_0^\infty \mathrm{d}\tilde{k}\, \tilde{k}^2\, u^*_{n'0}(\tilde{k}) u_{n0}(\tilde{k}) = \delta_{nn'} \,. \qquad (3.28)
$$

We start our analysis by Lorentz transforming the matrix element of Eq. (3.23):

$$
\begin{aligned}
&\langle V'; \boldsymbol{k}'_1, \mu'_1; \boldsymbol{k}'_2, \mu'_2; \mu'_\mathrm{e} | V; \boldsymbol{k}_{12}, n, j, \mu_j; \mu_\mathrm{e}\rangle \\
&\quad \xrightarrow{\Lambda} \quad \langle \bar{V}'; \bar{\boldsymbol{k}}'_1, \bar{\mu}'_1; \bar{\boldsymbol{k}}'_2, \bar{\mu}'_2; \bar{\mu}'_\mathrm{e} | \bar{V}; \bar{\boldsymbol{k}}_{12}, n, j, \bar{\mu}_j; \bar{\mu}_\mathrm{e}\rangle \,. \qquad (3.29)
\end{aligned}
$$

Here we have dropped the dependences on the (redundant) momenta $\boldsymbol{k}_\mathrm{e}$ and $\boldsymbol{k}'_\mathrm{e}$. From the transformation properties of velocity states under Lorentz transformations, Eq. (2.73), we can rewrite the transformed matrix element in terms of the original one (using the short-hand notation $R^{(\prime)}_{\mathrm{W_c}} \equiv R_{\mathrm{W_c}}(V^{(\prime)},\Lambda)$):

$$\begin{aligned}
&\langle \bar V'; \bar{\boldsymbol{k}}'_1, \bar\mu'_1; \bar{\boldsymbol{k}}'_2, \bar\mu'_2; \bar\mu'_{\mathrm{e}} | \bar V; \bar{\boldsymbol{k}}_{12}, n, j, \bar\mu_j; \bar\mu_{\mathrm{e}}\rangle \\
&\quad= \quad \langle \Lambda V'; \boldsymbol{R}'_{\mathrm{W_c}} k'_1, \mu'_1; \boldsymbol{R}'_{\mathrm{W_c}} k'_2, \mu'_2; \mu'_{\mathrm{e}} | \Lambda V; \boldsymbol{R}_{\mathrm{W_c}} k_{\mathrm{C}}; n, j, \mu_j; \mu_{\mathrm{e}}\rangle \\
&\qquad\quad \times D^{j_1 *}_{\mu'_1 \bar\mu'_1}\left[\underline{R}^{-1}_{\mathrm{W_c}}(V',\Lambda)\right] D^{j_2 *}_{\mu'_2 \bar\mu'_2}\left[\underline{R}^{-1}_{\mathrm{W_c}}(V',\Lambda)\right] D^{j_{\mathrm{e}} *}_{\mu'_{\mathrm{e}} \bar\mu'_{\mathrm{e}}}\left[\underline{R}^{-1}_{\mathrm{W_c}}(V',\Lambda)\right] \\
&\qquad\quad \times D^{j_{\mathrm{e}}}_{\mu_{\mathrm{e}} \bar\mu_{\mathrm{e}}}\left[\underline{R}^{-1}_{\mathrm{W_c}}(V,\Lambda)\right] D^{j}_{\mu_j \bar\mu_j}\left[\underline{R}^{-1}_{\mathrm{W_c}}(V,\Lambda)\right] \\
&\quad= \quad (2\pi)^{15/2} \sqrt{\frac{2\tilde k'^0_1 2\tilde k'^0_2}{2(\tilde k'^0_1 + \tilde k'^0_2)}} \sqrt{\frac{2k^0_{\mathrm{C}} 2k^0_{\mathrm{e}}}{(k^0_{\mathrm{C}} + k^0_{\mathrm{e}})^3}} \sqrt{\frac{2k'^0_{12} 2k'^0_{\mathrm{e}}}{(k'^0_{12} + k'^0_{\mathrm{e}})^3}} \\
&\qquad\quad \times V^0 \delta^3(\boldsymbol{V} - \boldsymbol{V}') \delta_{\mu_{\mathrm{e}} \mu'_{\mathrm{e}}} \delta^3\left(\boldsymbol{k}_{\mathrm{e}} - \boldsymbol{k}'_{\mathrm{e}}\right) \Psi_{n j \mu_j \mu'_1 \mu'_2}(\bar{\tilde{\boldsymbol{k}}}') \\
&\qquad\quad \times D^{j_1 *}_{\mu'_1 \bar\mu'_1}\left[\underline{R}^{-1}_{\mathrm{W_c}}(V,\Lambda)\right] D^{j_2 *}_{\mu'_2 \bar\mu'_2}\left[\underline{R}^{-1}_{\mathrm{W_c}}(V,\Lambda)\right] \\
&\qquad\quad \times D^{j}_{\mu_j \bar\mu_j}\left[\underline{R}^{-1}_{\mathrm{W_c}}(V,\Lambda)\right] \, .
\end{aligned} \tag{3.30}$$

Here we have used Lorentz invariance of the delta functions and the fact that energies are not affected by (Wigner) rotations of the momenta. Note that under a Lorentz transformation the cluster center-of-mass momenta undergo the same Wigner rotation as the center-of-mass momenta of the three-particle system:

$$\begin{aligned}
\bar{\tilde k}'_1 \quad &= \quad B^{-1}(\boldsymbol{R}_{\mathrm{W_c}}(V,\Lambda) w'_{12}) R_{\mathrm{Wc}}(V,\Lambda) k'_1 \\
&= \quad B^{-1}(\boldsymbol{R}_{\mathrm{W_c}}(V,\Lambda) w'_{12}) R_{\mathrm{W_c}}(V,\Lambda) B_{\mathrm{c}}(\boldsymbol{w}'_{12}) \tilde k'_1 \\
&= \quad R_{\mathrm{W_c}}(w'_{12}, R_{\mathrm{W_c}}(V,\Lambda)) \tilde k_1 \\
&\overset{(2.44)}{=} \quad R_{\mathrm{W_c}}(V,\Lambda) \tilde k'_1 \, .
\end{aligned} \tag{3.31}$$

Since a pure s-wave depends only on the magnitude of the three-momentum, which is not affected by a rotation, we have $\Psi_{n j \mu_j \mu'_1 \mu'_2}(\bar{\tilde{\boldsymbol{k}}}') = \Psi_{n j \mu_j \mu'_1 \mu'_2}(\tilde{\boldsymbol{k}}')$. Comparing Eq. (3.30) with Eq. (3.23) we can read off the transformation properties of the wave function under Lorentz transformations:

$$\begin{aligned}
&\Psi_{n j \mu_j \mu'_1 \mu'_2}(\tilde{\boldsymbol{k}}') \xrightarrow{\Lambda} \Psi_{n j \bar\mu_j \bar\mu'_1 \bar\mu'_2}(\bar{\tilde{\boldsymbol{k}}}') \\
&\qquad = \Psi_{n j \mu_j \mu'_1 \mu'_2}(\tilde{\boldsymbol{k}}') D^{j_1}_{\bar\mu'_1 \mu'_1}\left[\underline{R}_{\mathrm{W_c}}(V,\Lambda)\right] D^{j_2}_{\bar\mu'_2 \mu'_2}\left[\underline{R}_{\mathrm{W_c}}(V,\Lambda)\right] D^{j *}_{\bar\mu_j \mu_j}\left[\underline{R}_{\mathrm{W_c}}(V,\Lambda)\right] \, .
\end{aligned} \tag{3.32}$$

In App. C.3 we also derive the transformation properties of the Clebsch-Gordan coefficients under Lorentz transformations which read

$$\begin{aligned}
&C^{j\mu_j}_{j_1 \tilde\mu_1 j_2 \tilde\mu_2} \overset{\Lambda}{\rightarrow} C^{j \bar\mu_j}_{j_1 \bar{\tilde\mu}_1 j_2 \bar{\tilde\mu}_2} \\
&\qquad = C^{j\mu_j}_{j_1 \tilde\mu_1 j_2 \tilde\mu_2} D^{j *}_{\bar\mu_j \mu_j}\left[\underline{R}_{\mathrm{W_c}}(V,\Lambda)\right] D^{j_1}_{\bar{\tilde\mu}_1 \tilde\mu_1}[\underline{R}_{\mathrm{W_c}}(V,\Lambda)] D^{j_2}_{\bar{\tilde\mu}_2 \tilde\mu_2}[\underline{R}_{\mathrm{W_c}}(V,\Lambda)] \, .
\end{aligned} \tag{3.33}$$

3.4.3 Extension to Four-Body Hilbert Space

The procedure of embedding two-body interactions into a three-body Hilbert space can be easily generalized to a n-body Hilbert space. For our purposes we consider a four-body Hilbert space of a system consisting of the interacting pair 1 and 2, the spectator e and another massless spectator γ ('γ' stands for a photon). Instead of going explicitly through an analogous procedure as above we simply list the most important results which will be needed in the following sections. The total mass operator for the four-particle system is given by

$$\hat{M}_{\mathrm{Ce}\gamma} := \sqrt{\hat{\boldsymbol{k}}_{\mathrm{C}}^2 + \hat{m}_{\mathrm{C}}^2} + \sqrt{\hat{\boldsymbol{k}}_{\mathrm{e}}^2 + m_{\mathrm{e}}^2} + |\hat{\boldsymbol{k}}_\gamma| \,. \tag{3.34}$$

The two-body wave function is defined via the velocity-states matrix elements by

$$\begin{aligned} &\langle V'; \boldsymbol{k}'_1, \mu'_1; (\boldsymbol{k}'_2), \mu'_2; \boldsymbol{k}'_{\mathrm{e}}, \mu'_{\mathrm{e}}; \boldsymbol{k}'_\gamma, \mu'_\gamma | V; (\boldsymbol{k}_{12}); n, j, \mu_j; \boldsymbol{k}_{\mathrm{e}}, \mu_{\mathrm{e}}; \boldsymbol{k}_\gamma, \mu_\gamma \rangle \\ &= (2\pi)^{21/2} \sqrt{\frac{2\tilde{k}_1'^0 2\tilde{k}_2'^0}{2(\tilde{k}_1'^0 + \tilde{k}_2'^0)}} \sqrt{\frac{2k_{\mathrm{C}}^0 2k_{\mathrm{e}}^0 2k_\gamma^0}{(k_{\mathrm{C}}^0 + k_{\mathrm{e}}^0 + k_\gamma^0)^3}} \sqrt{\frac{2k_{12}'^0 2k_{\mathrm{e}}'^0 2k_\gamma'^0}{(k_{12}'^0 + k_{\mathrm{e}}'^0 + k_\gamma'^0)^3}} V^0 \\ &\quad \times \delta^3(\boldsymbol{V} - \boldsymbol{V}') \delta_{\mu_{\mathrm{e}} \mu'_{\mathrm{e}}} \delta^3\left(\boldsymbol{k}_{\mathrm{e}} - \boldsymbol{k}'_{\mathrm{e}}\right) (-\mathrm{g}_{\mu_\gamma \mu'_\gamma}) \delta^3\left(\boldsymbol{k}_\gamma - \boldsymbol{k}'_\gamma\right) \Psi_{n j \mu_j \mu'_1 \mu'_2}(\tilde{\boldsymbol{k}}') \,. \end{aligned} \tag{3.35}$$

The orthogonality and completeness relations of this basis vectors are given by

$$\begin{aligned} &\langle V'; \boldsymbol{k}'_{12}; n', j', \mu'_j; (\boldsymbol{k}'_{\mathrm{e}}), \mu'_{\mathrm{e}}; \boldsymbol{k}'_\gamma, \mu'_\gamma | V; \boldsymbol{k}_{12}, n, j, \mu_j; (\boldsymbol{k}_{\mathrm{e}}), \mu_{\mathrm{e}}; \boldsymbol{k}_\gamma, \mu_\gamma \rangle \\ &= (2\pi)^9 V^0 \delta^3(\boldsymbol{V} - \boldsymbol{V}') \frac{2k_{\mathrm{C}}^0 2k_{\mathrm{e}}^0}{(k_{\mathrm{C}}^0 + k_{\mathrm{e}}^0 + k_\gamma^0)^3} \delta^3(\boldsymbol{k}_{12} - \boldsymbol{k}'_{12}) \delta_{nn'} \delta_{jj'} \delta_{\mu_j \mu'_j} \\ &\quad \times \delta_{\mu_{\mathrm{e}} \mu'_{\mathrm{e}}} (-\mathrm{g}^{\mu_\gamma \mu'_\gamma}) 2k_\gamma^0 \delta^3(\boldsymbol{k}_\gamma - \boldsymbol{k}'_\gamma) \end{aligned} \tag{3.36}$$

and

$$\begin{aligned} \hat{1}_{\mathrm{Ce}\gamma} &= \frac{1}{(2\pi)^9} \int \frac{\mathrm{d}^3 V}{V^0} \frac{\mathrm{d}^3 k_{12}}{2k_{\mathrm{C}}^0} \frac{\mathrm{d}^3 k_\gamma}{2k_\gamma^0} \frac{(k_{\mathrm{C}}^0 + k_{\mathrm{e}}^0 + k_\gamma^0)^3}{2k_{\mathrm{e}}^0} \\ &\quad \times \sum_{n j \mu_j \mu_{\mathrm{e}} \mu_\gamma} (-\mathrm{g}^{\mu_\gamma \mu_\gamma}) |V; \boldsymbol{k}_{12}, n, j, \mu_j; (\boldsymbol{k}_{\mathrm{e}}), \mu_{\mathrm{e}}; \boldsymbol{k}_\gamma, \mu_\gamma \rangle \\ &\quad \times \langle V; \boldsymbol{k}_{12}, n, j, \mu_j; (\boldsymbol{k}_{\mathrm{e}}), \mu_{\mathrm{e}}; \boldsymbol{k}_\gamma, \mu_\gamma | \,, \end{aligned} \tag{3.37}$$

respectively.

3.4.4 Cluster Properties

We have already mentioned that the concept of macrocausality (or equivalently cluster separability) becomes questionable within a Bakamjian-Thomas construction for relativistic quantum mechanics of more than 2 particles. In this subsection we follow closely Ref. [KP91] and discuss the most simple non-trivial case on this issue, the (2+1)-problem of a pair C of interacting particles 1 and 2 and a non-interacting spectator e. What follows applies equally to 2 or more non-interacting spectators. Cluster separability requires that, if the spectator is separated by a sufficient large space-like distance from the cluster, then both, the cluster and the spectator, should behave as independent subsystems. In other words, all relevant physical properties of the (12e)-system should also hold for the (12)-subsystem. With relevant physical properties in the context of cluster separability we mean the relativistic transformation laws [KP91].

In order to find a mathematical formulation of the condition of cluster separability we consider a Hilbert space of the (2+1)-system, which is the tensor product of the Hilbert spaces of the cluster and the spectator. A unitary representation of the Poincaré group on this Hilbert space is then given by Eq. (2.63):

$$\hat{U}_{\mathrm{Ce}}\left(\underline{\Lambda},\underline{a}\right) := \hat{U}_{\mathrm{C}}\left(\underline{\Lambda},\underline{a}\right) \otimes \hat{U}_{\mathrm{e}}\left(\underline{\Lambda},\underline{a}\right) . \tag{3.38}$$

Here $\hat{U}_{\mathrm{C}}\left(\underline{\Lambda},\underline{a}\right)$ and $\hat{U}_{\mathrm{e}}\left(\underline{\Lambda},\underline{a}\right)$ are unitary representations associated with the interacting pair and the spectator, respectively. Both these representations are assumed to have the same relativistic transformation properties as the whole (Ce)-system. From Eq. (3.38) we can define translation operators by

$$\hat{T}_{\mathrm{C}}\left(\underline{a}\right) := \hat{U}_{\mathrm{C}}\left(1_2,\underline{a}\right) \otimes \hat{1}_{\mathrm{e}} \quad \text{and} \quad \hat{T}_{\mathrm{e}}\left(\underline{a}\right) := \hat{1}_{\mathrm{C}} \otimes \hat{U}_{\mathrm{e}}\left(1_2,\underline{a}\right) \tag{3.39}$$

that translate the interacting pair and the spectator by a^μ, respectively. Additionally, we consider an interacting representation $\hat{U}\left(\underline{\Lambda},\underline{a}\right)$ of the Poincaré group associated with the interacting (Ce)-system. This representation satisfies cluster separability if it satisfies the, so-called, *cluster condition* [KP91]:

$$\lim_{(b-c)^2\to-\infty}\langle\Psi|\hat{T}^\dagger_{\mathrm{C}}\left(\underline{\Lambda b}\right)\hat{T}^\dagger_{\mathrm{e}}\left(\underline{\Lambda c}\right)\left\{\hat{U}\left(\underline{\Lambda},\underline{a}\right)-\hat{U}_{\mathrm{Ce}}\left(\underline{\Lambda},\underline{a}\right)\right\}\hat{T}_{\mathrm{C}}\left(\underline{b}\right)\hat{T}_{\mathrm{e}}\left(\underline{c}\right)|\Psi\rangle = 0 . \tag{3.40}$$

This condition can be interpreted in the sense that for infinitely large space-like separations of the subsystems C and e, $\hat{U}\left(\underline{\Lambda},\underline{a}\right)$ becomes identical to the tensor-product representation $\hat{U}_{\mathrm{Ce}}\left(\underline{\Lambda},\underline{a}\right)$. For infinitesimal Poincaré transformations the cluster condition Eq. (3.40) can be written as a *cluster condition on the generators* [KP91]:

$$\lim_{(b-c)^2\to-\infty}\langle\Psi|\hat{T}^\dagger_{\mathrm{C}}\left(\underline{b}\right)\hat{T}^\dagger_{\mathrm{e}}\left(\underline{c}\right)\left\{\hat{G}-\hat{G}_{\mathrm{Ce}}\right\}\hat{T}_{\mathrm{C}}\left(\underline{b}\right)\hat{T}_{\mathrm{e}}\left(\underline{c}\right)|\Psi\rangle = 0 . \tag{3.41}$$

Here the infinitesimal generators $\hat{G}_{\mathrm{Ce}} \equiv \{\hat{P}^\mu_{\mathrm{Ce}}, \hat{M}^{\nu\lambda}_{\mathrm{Ce}}\}$ of the tensor-product representation, Eq. (3.38), are given by Eq. (2.64):

$$\hat{P}^\mu_{\mathrm{Ce}} = \hat{p}^\mu_{\mathrm{C}} \otimes \hat{1}_{\mathrm{e}} + \hat{1}_{\mathrm{C}} \otimes \hat{p}^\mu_{\mathrm{e}} \quad \text{and} \quad \hat{M}^{\nu\lambda}_{\mathrm{Ce}} = \hat{m}^{\nu\lambda}_{\mathrm{C}} \otimes \hat{1}_{\mathrm{e}} + \hat{1}_{\mathrm{C}} \otimes \hat{m}^{\nu\lambda}_{\mathrm{e}} . \tag{3.42}$$

In our case of the point form the generators of the cluster are

$$\hat{p}^\mu_{\mathrm{C}} = \hat{p}^\mu_{12} + \hat{p}^\mu_{\mathrm{int}} \quad \text{and} \quad \hat{m}^{\nu\lambda}_{\mathrm{C}} = \hat{m}^{\nu\lambda}_{12} = \hat{m}^{\nu\lambda}_{1} \otimes \hat{1}_2 + \hat{1}_1 \otimes \hat{m}^{\nu\lambda}_{2} . \tag{3.43}$$

$\hat{G} \equiv \{\hat{P}^\mu, \hat{M}^{\nu\lambda}\}$ are the generators formally obtained from the derivative of $\hat{U}\left(\underline{\Lambda},\underline{a}\right)$ with respect to the parameters for vanishing values of the parameters, cf. Eqs. (2.28) and (2.29).

The physical interpretation of the cluster condition, Eq. (3.41), is quite obvious [KP91]: cluster separability is satisfied if the total energy, linear and angular momentum of the (Ce)-system in the cluster limit is equal to the sum of the individual energies, linear and angular momenta of the cluster and the spectator, respectively.

With a condition for macrocausality at hand we are now able to investigate the cluster properties of the representation of the Poincaré group associated with the point-form Bakamjian-Thomas construction derived in the previous sections. The generator of interest in our point-form formulation is the interacting four-momentum operator given by Eq. (3.22). For simplicity, we can restrict our considerations (without loss of generality) to separation operators being pure spatial translations $\hat{T}_i(\underline{\boldsymbol{a}}) = \mathrm{e}^{\mathrm{i}\,\hat{\boldsymbol{p}}_i\cdot\boldsymbol{a}}$. Then the left-hand side of the cluster condition, Eq. (3.41), for the point-form Bakamjian-Thomas generators $\hat{P}^\mu$ of Eq. (3.22) reads

$$\begin{aligned}
&\lim_{|\boldsymbol{b}-\boldsymbol{c}|\to\infty} \langle\Psi|\mathrm{e}^{-\mathrm{i}\,(\hat{\boldsymbol{p}}_\mathrm{C}\cdot\boldsymbol{b}+\hat{\boldsymbol{p}}_\mathrm{e}\cdot\boldsymbol{c})}\left\{\hat{P}^\mu - \hat{P}^\mu_\mathrm{Ce}\right\}\mathrm{e}^{\mathrm{i}\,(\hat{\boldsymbol{p}}_\mathrm{C}\cdot\boldsymbol{b}+\hat{\boldsymbol{p}}_\mathrm{e}\cdot\boldsymbol{c})}|\Psi\rangle \\
&\quad = \lim_{|\boldsymbol{b}-\boldsymbol{c}|\to\infty} \langle\Psi|\mathrm{e}^{-\mathrm{i}\,(\hat{\boldsymbol{p}}_\mathrm{C}\cdot\boldsymbol{b}+\hat{\boldsymbol{p}}_\mathrm{e}\cdot\boldsymbol{c})}\left\{\hat{P}^\mu_\mathrm{int} - \hat{P}^\mu_\mathrm{12int,e}\right\}\mathrm{e}^{\mathrm{i}\,(\hat{\boldsymbol{p}}_\mathrm{C}\cdot\boldsymbol{b}+\hat{\boldsymbol{p}}_\mathrm{e}\cdot\boldsymbol{c})}|\Psi\rangle
\end{aligned} \tag{3.44}$$

where we have used that $\hat{P}^\mu = \hat{P}^\mu_\mathrm{12e} + \hat{P}^\mu_\mathrm{int}$ and $\hat{P}^\mu_\mathrm{Ce} = \hat{P}^\mu_\mathrm{12e} + \hat{P}^\mu_\mathrm{12int,e}$ from Eqs. (3.21) and (3.42), respectively. Since $\hat{P}^\mu_\mathrm{12int,e}$ commutes with $\hat{\boldsymbol{p}}_\mathrm{C}$ and $\hat{\boldsymbol{p}}_\mathrm{e}$ by definition, the exponentials cancel in the second term of Eq. (3.44):

$$\lim_{|\boldsymbol{b}-\boldsymbol{c}|\to\infty} \langle\Psi|\mathrm{e}^{-\mathrm{i}\,(\hat{\boldsymbol{p}}_\mathrm{C}\cdot\boldsymbol{b}+\hat{\boldsymbol{p}}_\mathrm{e}\cdot\boldsymbol{c})}\hat{P}^\mu_\mathrm{12int,e}\mathrm{e}^{\mathrm{i}\,(\hat{\boldsymbol{p}}_\mathrm{C}\cdot\boldsymbol{b}+\hat{\boldsymbol{p}}_\mathrm{e}\cdot\boldsymbol{c})}|\Psi\rangle = \langle\Psi|\hat{P}^\mu_\mathrm{12int,e}|\Psi\rangle\,. \tag{3.45}$$

The first term of Eq. (3.44) can be rewritten in terms of the operators $\hat{\boldsymbol{V}}$ and $\hat{\boldsymbol{k}}_\mathrm{e}$ with $\hat{k}_\mathrm{C} = (\sqrt{\hat{m}_\mathrm{C}^2 + \hat{\boldsymbol{k}}_\mathrm{e}^2}, -\hat{\boldsymbol{k}}_\mathrm{e})$ as

$$\begin{aligned}
&\lim_{|\boldsymbol{b}-\boldsymbol{c}|\to\infty} \quad \langle\Psi|\mathrm{e}^{-\mathrm{i}\,(\boldsymbol{B}_\mathrm{c}(\hat{\boldsymbol{V}})\hat{k}_\mathrm{C}\cdot\boldsymbol{b}+\boldsymbol{B}_\mathrm{c}(\hat{\boldsymbol{V}})\hat{k}_\mathrm{e}\cdot\boldsymbol{c})}\hat{M}_\mathrm{int}\hat{V}^\mu\,\mathrm{e}^{\mathrm{i}\,(\boldsymbol{B}_\mathrm{c}(\hat{\boldsymbol{V}})\hat{k}_\mathrm{C}\cdot\boldsymbol{b}+\boldsymbol{B}_\mathrm{c}(\hat{\boldsymbol{V}})\hat{k}_\mathrm{e}\cdot\boldsymbol{c})}|\Psi\rangle \\
&\quad = \quad \lim_{|\boldsymbol{b}|\to\infty} \langle\Psi|\hat{V}^\mu\,\mathrm{e}^{-\mathrm{i}\,\boldsymbol{B}_\mathrm{c}(\hat{\boldsymbol{V}})\hat{k}_\mathrm{C}\cdot\boldsymbol{b}}\hat{M}_\mathrm{int}\,\mathrm{e}^{\mathrm{i}\,\boldsymbol{B}_\mathrm{c}(\hat{\boldsymbol{V}})\hat{k}_\mathrm{C}\cdot\boldsymbol{b}}|\Psi\rangle\,.
\end{aligned} \tag{3.46}$$

Here we have used that $\hat{V}^\mu$ commutes with $\hat{\boldsymbol{k}}_\mathrm{e}$ and $\hat{m}_\mathrm{C} = \hat{m}_{12} + \hat{m}_\mathrm{int}$. We have further used that $\hat{M}_\mathrm{int}$ commutes with $\hat{V}^\mu$ and $\hat{\boldsymbol{k}}_\mathrm{e}$. Note that from Eq. (2.4) we have

$$\boldsymbol{B}_\mathrm{c}(\hat{\boldsymbol{V}})\hat{k}_\mathrm{C} = \sqrt{\hat{\boldsymbol{k}}_\mathrm{e}^2 + \hat{m}_\mathrm{C}^2}\,\hat{\boldsymbol{V}} - \hat{\boldsymbol{k}}_\mathrm{e} - \frac{\hat{V}^0 - 1}{\hat{\boldsymbol{V}}^2}\hat{\boldsymbol{V}}(\hat{\boldsymbol{V}}\cdot\hat{\boldsymbol{k}}_\mathrm{e})\,. \tag{3.47}$$

We observe that only the first term of this expression does not commute with $\hat{M}_\mathrm{int}$ since it involves the operator $\hat{\hat{\boldsymbol{k}}}$ which occurs in $\hat{m}_\mathrm{C}$, cf. Eq. (2.83). Using this, Eq. (3.46) can be further reduced to

$$\lim_{|\boldsymbol{b}|\to\infty} \langle\Psi|\hat{V}^\mu\,\mathrm{e}^{-\mathrm{i}\,\sqrt{\hat{m}_\mathrm{C}^2+\hat{\boldsymbol{k}}_\mathrm{e}^2}\,\hat{\boldsymbol{V}}\cdot\boldsymbol{b}}\hat{M}_\mathrm{int}\,\mathrm{e}^{\mathrm{i}\,\sqrt{\hat{m}_\mathrm{C}^2+\hat{\boldsymbol{k}}_\mathrm{e}^2}\,\hat{\boldsymbol{V}}\cdot\boldsymbol{b}}|\Psi\rangle\,. \tag{3.48}$$

This expression has a similar structure as a corresponding expression in an instant-form analysis of Ref. [KP91]. Therefore, we can use similar arguments as therein: under certain assumptions (for details we refer to [KP91]) about the regularity of the interaction and the wave function it can be shown that expression (3.48) vanishes, whereas in general Eq. (3.45) does not. This represents a violation of the cluster condition, Eq. (3.41), for the Bakamjian-Thomas generators $\hat{P}^\mu$ of Eq. (3.22).

The vanishing of (3.48) indicates the vanishing of the interaction between particles 1 and 2 in the limit where the non-interacting spectator is separated by an infinite large space-like distance. This means that the physical properties of the interacting pair are not independent of the non-interacting spectator.

The problem is inherent in the definition of the cluster wave functions from velocity states for more than 2 particles, see, e.g., Eq. (3.23). In particular, the wave function depends on the energy of the spectator which is reflected in a k_{e}^0-dependence of the normalization factors of Eq. (3.27). Likewise the wave function changes in the presence of additional non-interacting particles. This change is essentially proportional to the fraction of the cluster binding energy over the invariant mass of the whole system. This indicates that, if the invariant mass of the whole system is made sufficiently large, the effects of wrong cluster separability properties should be minimized or in particular cases even be eliminated.

3.5 Quantum Field Theoretical Vertex Interactions

Up to now we discussed only instantaneous interactions. In order to set up a relativistic multi-channel problem we need interactions which describe particle creation and annihilation. The definition of such quantum field theoretical vertex interactions within our point-form Bakamjian-Thomas framework is the subject of this section. It relies on the ideas of Refs. [Kli03a, Kra01].

3.5.1 Field Operators

The first step towards a field theoretical vertex interaction is the construction of field operators. In the present section we will consider only fermion-photon vertices with the fermion field being a (anti-)quark, nucleon or electron field.

Dirac Fields

The field operators for a charged massive spin-1/2 fermion field read

$$\hat{\psi}\,(x) = \frac{1}{(2\pi)^3} \int \frac{\mathrm{d}^3 p}{2p^0} \sum_{\sigma=\pm\frac{1}{2}} \Big(\mathrm{e}^{\mathrm{i}p\cdot x} v_\sigma(\boldsymbol{p}) \hat{d}^\dagger_\sigma(\boldsymbol{p}) + \mathrm{e}^{-\mathrm{i}p\cdot x} u_\sigma(\boldsymbol{p}) \hat{c}_\sigma(\boldsymbol{p}) \Big) \tag{3.49}$$

and

$$\hat{\bar{\psi}}\,(x) = \frac{1}{(2\pi)^3} \int \frac{\mathrm{d}^3 p}{2p^0} \sum_{\sigma=\pm\frac{1}{2}} \Big(\mathrm{e}^{-\mathrm{i}p\cdot x} \bar{v}_\sigma(\boldsymbol{p}) \hat{d}_\sigma(\boldsymbol{p}) + \mathrm{e}^{\mathrm{i}p\cdot x} \bar{u}_\sigma(\boldsymbol{p}) \hat{c}^\dagger_\sigma(\boldsymbol{p}) \Big)\,. \tag{3.50}$$

$\hat{\psi}_\alpha\,(x)$ with $\alpha = 1, \ldots, 4$ transforms under Poincaré transformations with the four-dimensional matrix representation of the $\mathrm{SL}(2,\mathbb{C})$, which has been introduced in Eq. (2.23):

$$\hat{U}(\underline{\Lambda}, \underline{a})\, \hat{\psi}_\alpha\,(x)\ \hat{U}^\dagger(\underline{\Lambda}, \underline{a}) = S_{\alpha\beta}(\underline{\Lambda}^{-1})\, \hat{\psi}_\beta\,(\Lambda x + a)\,. \tag{3.51}$$

With the help of Eq. (B.13) the transformation properties of the adjoint field operators follow immediately:

$$\hat{U}(\underline{\Lambda}, \underline{a})\, \hat{\bar{\psi}}_\alpha\,(x)\ \hat{U}^\dagger(\underline{\Lambda}, \underline{a}) = \hat{\bar{\psi}}_\beta\,(\Lambda x + a)\, S_{\beta\alpha}(\underline{\Lambda})\,. \tag{3.52}$$

$u_\sigma(\boldsymbol{p})_\alpha$ and $v_\sigma(\boldsymbol{p})_\alpha$ are the Dirac four-spinors defined by the action of a canonical boost on the spinors in the rest frame:

$$\begin{aligned} u_\sigma(\boldsymbol{p})_\alpha &= S_{\alpha\beta}[\underline{B}_c(\boldsymbol{v})]u_\sigma(\boldsymbol{0})_\beta\,, &(3.53)\\ v_\sigma(\boldsymbol{p})_\alpha &= S_{\alpha\beta}[\underline{B}_c(\boldsymbol{v})]v_\sigma(\boldsymbol{0})_\beta\,. &(3.54)\end{aligned}$$

They correspond to fermion and anti-fermion solutions of the Dirac equation, respectively:

$$(\gamma^\mu p_\mu - m)\, u_\sigma(\boldsymbol{p}) = 0 \quad \text{and} \quad (\gamma^\mu p_\mu + m)\, v_\sigma(\boldsymbol{p}) = 0\,. \tag{3.55}$$

The explicit forms of the spinors are fixed by the representation used for the γ-matrices. In the standard representation, which will be used throughout this work, the spinors are given in App. B.1. The adjoint Dirac spinors defined by $\bar{u}_\sigma(\boldsymbol{p}) := u^\dagger_\sigma(\boldsymbol{p})\gamma^0$ and $\bar{v}_\sigma(\boldsymbol{p}) := v^\dagger_\sigma(\boldsymbol{p})\gamma^0$ satisfy the adjoint Dirac equation:

$$\bar{u}_\sigma(\boldsymbol{p})\,(\gamma^\mu p_\mu - m) = 0 \quad \text{and} \quad \bar{v}_\sigma(\boldsymbol{p})\,(\gamma^\mu p_\mu + m) = 0\,. \tag{3.56}$$

The operators $\hat{c}^\dagger_\sigma(\boldsymbol{p})$ $(\hat{c}_\sigma(\boldsymbol{p}))$ and $\hat{d}^\dagger_\sigma(\boldsymbol{p})$ $(\hat{d}_\sigma(\boldsymbol{p}))$ are creation (annihilation) operators for fermions and anti-fermions, respectively. They act on the, so-called, *Fock space* which is the direct sum over all tensor products of single-particle Hilbert spaces. The vacuum state $|0\rangle$ of this Fock space is defined via the action of the annihilation operators:

$$\hat{c}_\sigma(\boldsymbol{p})|0\rangle = \hat{d}_\sigma(\boldsymbol{p})|0\rangle = 0\,. \tag{3.57}$$

A n-particle tensor-product state containing (anti-)fermions is obtained by applying n creation operators for (anti-)fermions to the vacuum state. Hence, for a n-fermion state, for example, we have

$$\hat{c}^\dagger_{\sigma_1}(\boldsymbol{p}_1)\hat{c}^\dagger_{\sigma_2}(\boldsymbol{p}_2)\cdots\hat{c}^\dagger_{\sigma_n}(\boldsymbol{p}_n)|0\rangle = |\boldsymbol{p}_1,\sigma_1;\boldsymbol{p}_2,\sigma_2;\ldots;\boldsymbol{p}_n,\sigma_n\rangle\,. \tag{3.58}$$

For each anti-fermion occurring in Eq. (3.58) the corresponding fermion operator $\hat{c}^\dagger_{\sigma_i}(\boldsymbol{p}_i)$ has to be replaced by $\hat{d}^\dagger_{\sigma_i}(\boldsymbol{p}_i)$. The creation and annihilation operators satisfy the following anti-commutation relations:

$$\{\hat{c}_\sigma(\boldsymbol{p}),\hat{c}^\dagger_{\sigma'}(\boldsymbol{p}')\} = \{\hat{d}_\sigma(\boldsymbol{p}),\hat{d}^\dagger_{\sigma'}(\boldsymbol{p}')\} = (2\pi)^3 2p^0\delta^3\left(\boldsymbol{p}-\boldsymbol{p}'\right)\delta_{\sigma\sigma'}\,. \tag{3.59}$$

They are fixed by the normalization of the massive one-particle states Eq. (2.51). All other anti-commutators vanish.

Maxwell Field

A field operator for a neutral massless spin-1 boson field, such as a photon, is given by

$$\hat{A}^\mu(x) = \frac{1}{(2\pi)^3}\int\frac{\mathrm{d}^3p}{2|\boldsymbol{p}|}\sum_{\lambda=0}^{3}(-\mathrm{g}^{\lambda\lambda})\,\left(\mathrm{e}^{\mathrm{i}p\cdot x}\epsilon^\mu_\lambda(\boldsymbol{p})\hat{a}^\dagger_\lambda(\boldsymbol{p}) + \mathrm{e}^{-\mathrm{i}p\cdot x}\epsilon^{*\mu}_\lambda(\boldsymbol{p})\hat{a}_\lambda(\boldsymbol{p})\right)\,. \tag{3.60}$$

The field operator $\hat{A}^\mu(x)$ transforms under a Poincaré transformation with the usual four-dimensional matrix representation of the Lorentz group Eq. (2.6):

$$\hat{U}(\underline{\Lambda},\underline{a})\,\hat{A}^\mu(x)\,\hat{U}^\dagger(\underline{\Lambda},\underline{a}) = \left(\Lambda^{-1}\right)^\mu{}_\nu\,\hat{A}^\nu(\Lambda x + a). \tag{3.61}$$

The appropriately orthonormalized photon polarization vectors $\epsilon^\mu_\lambda(\boldsymbol{p})$ are most conveniently expressed as the components of the helicity boost matrix $\epsilon^\mu_\lambda(\boldsymbol{p}) = B_\mathrm{h}(\boldsymbol{p})^\mu{}_\lambda$ [Kli03b], which satisfy the completeness relation

$$\sum_{\lambda=0}^{3} \epsilon^\mu_\lambda(\boldsymbol{p})(-\mathrm{g}^{\lambda\lambda})\,\epsilon^{*\nu}_\lambda(\boldsymbol{p}) = -\mathrm{g}^{\mu\nu}\,. \tag{3.62}$$

The operators $\hat{a}^\dagger_\lambda(\boldsymbol{p})$ and $\hat{a}_\lambda(\boldsymbol{p})$ are photon creation and annihilation operators, respectively. They satisfy the commutation relations

$$[\hat{a}_\lambda(\boldsymbol{p}), \hat{a}^\dagger_{\lambda'}(\boldsymbol{p}')] = (2\pi)^3 2p^0 \delta^3\left(\boldsymbol{p}-\boldsymbol{p}'\right)(-\mathrm{g}_{\lambda\lambda'})\,. \tag{3.63}$$

All other commutators vanish. $\hat{a}_\lambda$ annihilates the vacuum state $|0\rangle$:

$$\hat{a}_\lambda(\boldsymbol{p})|0\rangle = 0\,. \tag{3.64}$$

3.5.2 Vertex Operators from Interaction Densities

In a velocity-state basis the Bakamjian-Thomas type four-momentum operator, Eq. (3.5), becomes diagonal in the total four-velocity V^μ. This is a special feature of the Bakamjian-Thomas construction which, in general, does not hold for arbitrary interacting relativistic quantum theories. It is, in particular, not possible to factorize the four-momentum operator of an interacting point-form quantum field theory into a product of a four-velocity operator and an interacting mass operator, cf. Ref. [BKSZ08]. Therefore, vertex operators responsible for photon emission and absorption cannot directly be taken from point-form quantum electrodynamics. One rather has to make the approximation that the total four-velocity of the system is conserved at the electromagnetic vertices to end up with a Bakamjian-Thomas type mass operator. In Ref. [Kli03a] it has been demonstrated in some detail that this is a natural way to implement general field theoretical vertex interactions into a Bakamjian-Thomas type framework.

Constituents

We start our discussion by looking at the interaction of a photon field with the constituents and the electron. To this end we consider a field theoretical interaction density $\hat{\mathcal{L}}_\mathrm{int}(x)$ for spinor quantum electrodynamics [BD64]. It is given by the normal ordered product of the field operators defined above:

$$\begin{aligned}\hat{\mathcal{L}}_\mathrm{int}(x) \quad &:= \quad -:\hat{J}^\mu_1(x)\hat{A}_\mu(x): - :\hat{J}^\mu_2(x)\hat{A}_\mu(x): \\ &\qquad -|\,\mathrm{e}\,|\,Q_\mathrm{e} : \hat{\bar{\psi}}_\mathrm{e}(x)\gamma^\mu\hat{\psi}_\mathrm{e}(x)\hat{A}_\mu(x): \,.\end{aligned} \tag{3.65}$$

$\hat{\mathcal{L}}_\mathrm{int}(x)$ describes the coupling of a photon field to the 2 spin-1/2 constituent fields and to the electron field. The $\hat{J}^\mu_i(x)$ are current operators of the constituents and are given for point-like constituents like, e.g. quarks, explicitly by $\hat{J}^\mu_\mathrm{q}(x) = |\,\mathrm{e}\,|\,Q_\mathrm{q}\hat{\bar{\psi}}_\mathrm{q}(x)\gamma^\mu\hat{\psi}_\mathrm{q}(x)$. The transformation properties of the fields, Eqs. (3.51) and (3.52), together with Eq. (B.15) imply that the fermion current of the form $\hat{\bar{\psi}}(x)\gamma^\mu\hat{\psi}(x)$ transforms like a vector field (cf. Eq. (3.61)). Furthermore, it satisfies current conservation:

$$\frac{\partial}{\partial x^\mu}\hat{J}^\mu_\mathrm{q}(x) = 0\,. \tag{3.66}$$

We require a general current operator $\hat{J}_i^\mu(x)$ for non-point-like objects such as nucleons to have the same covariance and continuity properties as $\hat{J}_{\mathrm{q}}^\mu(x)$. Consequently, $\hat{\mathcal{L}}_{\mathrm{int}}(x)$ transforms like a Lorentz scalar:

$$\hat{U}(\underline{\Lambda}, \underline{a})\, \hat{\mathcal{L}}_{\mathrm{int}}(x)\, \hat{U}^\dagger(\underline{\Lambda}, \underline{a}) = \hat{\mathcal{L}}_{\mathrm{int}}(\Lambda x + a)\,. \tag{3.67}$$

From the interaction Lagrangean density operator we can immediately construct the interaction part of the energy-momentum tensor operator, which reads $\hat{\mathcal{T}}_{\mathrm{int}}^{\mu\nu}(x) = -\mathrm{g}^{\mu\nu}\hat{\mathcal{L}}_{\mathrm{int}}(x)$. We have already seen in Sec. 3.2 that the space-like hypersurface of Minkowski space that is left invariant under the point-form kinematic group is the forward hyperboloid $x^\mu x_\mu = \tau^2$. In a point-form quantum field theory obtained from canonical quantization this hyperboloid represents the field quantization surface on which the canonical (anti-)commutation relations on the field operators $\hat{\psi}(x)$, $\hat{\bar{\psi}}(x)$ and $\hat{A}^\mu(x)$ are imposed [BKSZ08]. Accordingly, the interaction four-momentum operator in a point-form quantum field theory is obtained by integrating $\hat{\mathcal{T}}_{\mathrm{int}}^{\mu\nu}(x)$ over the forward hyperboloid [Kli03a, BKSZ08]:

$$\hat{P}_{\mathrm{int}}^\mu = -\int 2\mathrm{d}^4x\, \delta(x^\mu x_\mu - \tau^2)\, \theta(x^0)\, x^\mu \hat{\mathcal{L}}_{\mathrm{int}}(x)\,. \tag{3.68}$$

The correct transformation properties of $\hat{P}_{\mathrm{int}}^\mu$ under Poincaré transformations, Eq. (2.30), follow immediately from Eq. (3.67) and the invariance of the hypersurface element $\mathrm{d}^4x\, \delta(x^\mu x_\mu - \tau^2)\, \theta(x^0)$. Since $\hat{\mathcal{L}}_{\mathrm{int}}(x)$ is a local field operator that transforms like a Lorentz-scalar density it can be shown that the Lie algebra for translations, Eq. (2.10), is satisfied [Kli03a].

Now consider particular matrix elements of this interacting momentum operator between velocity states:

$$\begin{aligned}
&\langle V'; \boldsymbol{k}_1', \mu_1'; \boldsymbol{k}_2', \mu_2'; \boldsymbol{k}_{\mathrm{e}}', \mu_{\mathrm{e}}'; \boldsymbol{k}_\gamma', \mu_\gamma' | \hat{P}_{\mathrm{int}}^\mu | V; \boldsymbol{k}_1, \mu_1; \boldsymbol{k}_2, \mu_2; \boldsymbol{k}_{\mathrm{e}}, \mu_{\mathrm{e}}\rangle \\
&\quad = \quad -\langle V'; \boldsymbol{k}_1', \mu_1'; \boldsymbol{k}_2', \mu_2'; \boldsymbol{k}_{\mathrm{e}}', \mu_{\mathrm{e}}'; \boldsymbol{k}_\gamma', \mu_\gamma' | \hat{\mathcal{L}}_{\mathrm{int}}(0) | V; \boldsymbol{k}_1, \mu_1; \boldsymbol{k}_2, \mu_2; \boldsymbol{k}_{\mathrm{e}}, \mu_{\mathrm{e}}\rangle \\
&\qquad\quad \times \int 2\, \mathrm{d}^4x\, \delta(x^\mu x_\mu - \tau^2)\, \theta(x^0)\, x^\mu\, \mathrm{e}^{-\mathrm{i}(M_{12\mathrm{e}\gamma}' V' - M_{12\mathrm{e}} V)\cdot x}\,.
\end{aligned} \tag{3.69}$$

Here we have used the transformation properties of the Lagrangean density and the velocity states under space-time translations, Eqs. (3.67) and (2.75), respectively.

In order to find a Bakamjian-Thomas-type mass operator from $\hat{P}_{\mathrm{int}}^\mu$ that commutes with the velocity operator we have to assume the matrix elements in Eq. (3.69) to be diagonal in V and V'. For $\boldsymbol{V} = \boldsymbol{V}'$ the integral in Eq. (3.69) can be evaluated and one finds

$$\begin{aligned}
&\langle V; \boldsymbol{k}_1', \mu_1'; \boldsymbol{k}_2', \mu_2'; \boldsymbol{k}_{\mathrm{e}}', \mu_{\mathrm{e}}'; \boldsymbol{k}_\gamma', \mu_\gamma' | \hat{\mathcal{L}}_{\mathrm{int}}(0) | V; \boldsymbol{k}_1, \mu_1; \boldsymbol{k}_2, \mu_2; \boldsymbol{k}_{\mathrm{e}}, \mu_{\mathrm{e}}\rangle \\
&\qquad \times \int 2\mathrm{d}^4x\, \delta(x^\mu x_\mu - \tau^2)\, \theta(x^0)\, x^\mu\, \mathrm{e}^{-\mathrm{i}(M_{12\mathrm{e}\gamma}' - M_{12\mathrm{e}})V\cdot x} \\
&\quad = \quad f_{\mathrm{v}}(|M_{12\mathrm{e}\gamma}' - M_{12\mathrm{e}}|)\, V^\mu \\
&\qquad \times \langle \boldsymbol{k}_1', \mu_1'; \boldsymbol{k}_2', \mu_2'; \boldsymbol{k}_{\mathrm{e}}', \mu_{\mathrm{e}}'; \boldsymbol{k}_\gamma', \mu_\gamma' | \hat{\mathcal{L}}_{\mathrm{int}}(0) | \boldsymbol{k}_1, \mu_1; \boldsymbol{k}_2, \mu_2; \boldsymbol{k}_{\mathrm{e}}, \mu_{\mathrm{e}}\rangle\,.
\end{aligned} \tag{3.70}$$

The vertex factor $f_{\mathrm{v}}(|M_{12\mathrm{e}\gamma}' - M_{12\mathrm{e}}|)$ is a known function (for its explicit form we refer to Ref. [Kli03a]), but it might as well be replaced by a phenomenological function to compensate for the neglect of the contributions of terms that are off-diagonal in the four-velocity, as well as regulate the integrals, if necessary [Kra01]. These are, however, not our primary objectives here. Hence, we set $f_{\mathrm{v}}(|M'_{12\mathrm{e}\gamma} - M_{12\mathrm{e}}|) = 1$ in the following. By separating the four-velocity V^μ in Eq. (3.70), the remaining expression can be used to define the matrix elements of the *electromagnetic vertex operators* $K^\dagger$ and K between velocity states:

$$\begin{aligned}
&\langle V'; \boldsymbol{k}'_1, \mu'_1; \boldsymbol{k}'_2, \mu'_2; \boldsymbol{k}'_{\mathrm{e}}, \mu'_{\mathrm{e}}; \boldsymbol{k}'_\gamma, \mu'_\gamma | \hat{K}^\dagger | V; \boldsymbol{k}_1, \mu_1; \boldsymbol{k}_2, \mu_2; \boldsymbol{k}_{\mathrm{e}}, \mu_{\mathrm{e}} \rangle \\
&\quad \equiv \quad \langle V; \boldsymbol{k}_{\mathrm{e}}, \mu_{\mathrm{e}}; \boldsymbol{k}_1, \mu_1; \boldsymbol{k}_2, \mu_2 | \hat{K} | V'; \boldsymbol{k}'_{\mathrm{e}}, \mu'_{\mathrm{e}}; \boldsymbol{k}'_1, \mu'_1; \boldsymbol{k}'_2, \mu'_2; \boldsymbol{k}'_\gamma, \mu'_\gamma \rangle^* \\
&\quad := \quad \frac{(-1)(2\pi)^3}{\sqrt{M'^3_{12\mathrm{e}\gamma} M^3_{12\mathrm{e}}}} V^0 \delta^3(\boldsymbol{V} - \boldsymbol{V}') \\
&\qquad \times \langle \boldsymbol{k}'_1, \mu'_1; \boldsymbol{k}'_2, \mu'_2; \boldsymbol{k}'_{\mathrm{e}}, \mu'_{\mathrm{e}}; \boldsymbol{k}'_\gamma, \mu'_\gamma | \hat{\mathcal{L}}_{\mathrm{int}}(0) | \boldsymbol{k}_1, \mu_1; \boldsymbol{k}_2, \mu_2; \boldsymbol{k}_{\mathrm{e}}, \mu_{\mathrm{e}} \rangle
\end{aligned} \tag{3.71}$$

with

$$\begin{aligned}
&\langle \boldsymbol{k}'_1, \mu'_1; \boldsymbol{k}'_2, \mu'_2; \boldsymbol{k}'_{\mathrm{e}}, \mu'_{\mathrm{e}}; \boldsymbol{k}'_\gamma, \mu'_\gamma | \hat{\mathcal{L}}_{\mathrm{int}}(0) | \boldsymbol{k}_1, \mu_1; \boldsymbol{k}_2, \mu_2; \boldsymbol{k}_{\mathrm{e}}, \mu_{\mathrm{e}} \rangle \\
&\quad = \quad (2\pi)^6 \, |\,\mathrm{e}\,| \, Q_{\mathrm{e}} \, \bar{u}_{\mu'_{\mathrm{e}}}(\boldsymbol{k}'_{\mathrm{e}}) \gamma_\nu u_{\mu_{\mathrm{e}}}(\boldsymbol{k}_{\mathrm{e}}) \, \epsilon^\nu_{\mu'_\gamma}(\boldsymbol{k}'_\gamma) \, \delta_{\mu_1 \mu'_1} 2k_1^0 \delta^3(\boldsymbol{k}'_1 - \boldsymbol{k}_1) \\
&\qquad\qquad \times \delta_{\mu_2 \mu'_2} 2k_2^0 \delta^3(\boldsymbol{k}'_2 - \boldsymbol{k}_2) \\
&\qquad\quad + (2\pi)^6 J_{1\nu}(\boldsymbol{k}'_1, \mu'_1; \boldsymbol{k}_1, \mu_1) \epsilon^\nu_{\mu'_\gamma}(\boldsymbol{k}'_\gamma) \, \delta_{\mu_{\mathrm{e}} \mu'_{\mathrm{e}}} 2k_{\mathrm{e}}^0 \delta^3(\boldsymbol{k}'_e - \boldsymbol{k}_e) \\
&\qquad\qquad \times \delta_{\mu_2 \mu'_2} 2k_2^0 \delta^3(\boldsymbol{k}'_2 - \boldsymbol{k}_2) \\
&\qquad\quad + (2\pi)^6 J_{2\nu}(\boldsymbol{k}'_2, \mu'_2; \boldsymbol{k}_2, \mu_2) \, \epsilon^\nu_{\mu'_\gamma}(\boldsymbol{k}'_\gamma) \, \delta_{\mu_{\mathrm{e}} \mu'_{\mathrm{e}}} 2k_{\mathrm{e}}^0 \delta^3(\boldsymbol{k}'_e - \boldsymbol{k}_e) \\
&\qquad\qquad \times \delta_{\mu_1 \mu'_1} 2k_1^0 \delta^3(\boldsymbol{k}'_1 - \boldsymbol{k}_1) \, .
\end{aligned} \tag{3.72}$$

The factor $V^0/\sqrt{M'^3_{12\mathrm{e}\gamma} M^3_{12\mathrm{e}}}$ in Eq. (3.71) is derived from the requirement that an analogous procedure for the kinetic term in the Lagrangean provides the usual (kinetic) mass term [Lec03]. The detailed derivation of Eq. (3.72) is demonstrated in App. D.1. Here $J_i^\mu(\boldsymbol{k}'_i, \mu'_i; \boldsymbol{k}_i, \mu_i) := \langle \boldsymbol{k}'_i, \mu'_i | \hat{J}_i^\mu(0) | \boldsymbol{k}_i, \mu_i \rangle$ are the constituent currents which are given for the point-like (structureless) particle case of a quark and an antiquark by the expressions

$$J_{\mathrm{q}}^\mu(\boldsymbol{k}'_{\mathrm{q}}, \mu'_{\mathrm{q}}; \boldsymbol{k}_{\mathrm{q}}, \mu_{\mathrm{q}}) = |\,\mathrm{e}\,| \, Q_{\mathrm{q}} \bar{u}_{\mu'_{\mathrm{q}}}(\boldsymbol{k}'_{\mathrm{q}}) \gamma^\mu u_{\mu_{\mathrm{q}}}(\boldsymbol{k}_{\mathrm{q}}) \tag{3.73}$$

and

$$J_{\bar{\mathrm{q}}}^\mu(\boldsymbol{k}'_{\bar{\mathrm{q}}}, \mu'_{\bar{\mathrm{q}}}; \boldsymbol{k}_{\bar{\mathrm{q}}}, \mu_{\bar{\mathrm{q}}}) = -\,|\,\mathrm{e}\,| \, Q_{\bar{\mathrm{q}}} \bar{v}_{\mu_{\bar{\mathrm{q}}}}(\boldsymbol{k}_{\bar{\mathrm{q}}}) \gamma^\mu v_{\mu'_{\bar{\mathrm{q}}}}(\boldsymbol{k}'_{\bar{\mathrm{q}}}) \, , \tag{3.74}$$

respectively. For non-point-like constituents like nucleons the corresponding current matrix elements are given by

$$J_{\mathrm{N}}^\mu(\boldsymbol{k}'_{\mathrm{N}}, \mu'_{\mathrm{N}}; \boldsymbol{k}_{\mathrm{N}}, \mu_{\mathrm{N}}) = |\,\mathrm{e}\,| \, \bar{u}_{\mu'_{\mathrm{N}}}(\boldsymbol{k}'_{\mathrm{N}}) \left[F_1^{\mathrm{N}}(Q_{\mathrm{N}}^2) \gamma^\mu + F_2^{\mathrm{N}}(Q_{\mathrm{N}}^2) \frac{\mathrm{i}\, q_{\mathrm{N}\nu} \sigma^{\mu\nu}}{2m_{\mathrm{N}}} \right] u_{\mu_{\mathrm{N}}}(\boldsymbol{k}_{\mathrm{N}}) \tag{3.75}$$

with N ≡ (p, n) standing for ‘proton’ and ‘neutron’, respectively. The electromagnetic structure of the nucleons is described by Dirac and Pauli form factors

$F_1^{\mathrm{N}}(Q_{\mathrm{N}}^2)$ and $F_2^{\mathrm{N}}(Q_{\mathrm{N}}^2)$, respectively, which are functions of the square of the four-momentum transfer on the constituents defined by[4]

$$q_{\mathrm{N}} := k'_{\mathrm{N}} - k_{\mathrm{N}}\,, \quad -q_{\mathrm{N}}^{\mu} q_{\mathrm{N}\mu} =: Q_{\mathrm{N}}^2\,. \tag{3.76}$$

Eq. (3.75) is the most general expression for an electromagnetic current of an extended spin-1/2 object satisfying current conservation

$$q_{\mathrm{N}\mu} J_{\mathrm{N}}^{\mu}(\boldsymbol{k}'_{\mathrm{N}}, \mu'_{\mathrm{N}}; \boldsymbol{k}_{\mathrm{N}}, \mu_{\mathrm{N}}) = 0 \tag{3.77}$$

and Lorentz covariance, cf. App. B.1.2 (for a derivation of the expression (3.75) we refer to, e.g., Ref. [AH03]). The operator K ($K^{\dagger}$) describes the annihilation (creation) of a photon by the constituents 1 and 2 and by the electron. In the following chapter we will see how a point-form Bakamjian-Thomas-type mass operator is constructed from these vertex operators. The prescription, Eq. (3.71), is a very natural way to introduce field theoretical vertex interactions into the Bakamjian-Thomas framework. It preserves the Lorentz structure of field theoretical vertex interactions. However, due to the *overall* velocity conserving delta function $\delta^3(\boldsymbol{V} - \boldsymbol{V}')$ and the kinematical factor $1/\sqrt{M'^3_{\mathrm{e}12} M^3_{\mathrm{e}12\gamma}}$, the locality of the vertex is violated. These quantities do not only depend on the kinematics at the vertex, but also on the kinematics of the spectator particle(s).

Bound State

We can also define a Lagrangean density $\mathcal{L}^{\mathrm{C}}_{\mathrm{int}}(x)$ which describes the coupling of the photon field to the electron and to the bound state:

$$\hat{\mathcal{L}}^{\mathrm{C}}_{\mathrm{int}}(x) := -\,|\,\mathrm{e}\,|\, Q_{\mathrm{e}} : \hat{\bar{\psi}}_{\mathrm{e}}(x) \gamma^{\mu} \hat{\psi}_{\mathrm{e}}(x) \hat{A}_{\mu}(x) : - : \hat{J}^{\mu}_{\mathrm{C}}(x) \hat{A}_{\mu}(x) : \,. \tag{3.78}$$

In a similar way as above we can define vertex operators that describe the emission and absorption of a photon by the bound state. To distinguish them from the vertex operators for the constituents we will denote them by $\hat{K}^{\mathrm{C}\dagger}$ and $\hat{K}^{\mathrm{C}}$. They are defined by

$$\begin{aligned}
&\langle V'; \boldsymbol{k}'_{\mathrm{e}}, \mu'_{\mathrm{e}}; \boldsymbol{k}'_{\mathrm{C}}, \mu'_j; \boldsymbol{k}'_{\gamma}, \mu'_{\gamma} | \hat{K}^{\mathrm{C}\dagger} | V; \boldsymbol{k}_{\mathrm{e}}, \mu_{\mathrm{e}}; \boldsymbol{k}_{\mathrm{C}}, \mu_j \rangle \\
&\quad \equiv \quad \langle V; \boldsymbol{k}_{\mathrm{e}}, \mu_{\mathrm{e}}; \boldsymbol{k}_{\mathrm{C}}, \mu_j | \hat{K}^{\mathrm{C}} | V'; \boldsymbol{k}'_{\mathrm{e}}, \mu'_{\mathrm{e}}; \boldsymbol{k}'_{\mathrm{C}}, \mu'_j; \boldsymbol{k}'_{\gamma}, \mu'_{\gamma} \rangle^{*} \\
&\quad := \quad \frac{(-1)(2\pi)^3}{\sqrt{M'^3_{\mathrm{eC}} M^3_{\mathrm{eC}\gamma}}} V^0 \delta^3(\boldsymbol{V} - \boldsymbol{V}') \\
&\qquad\qquad \times \langle \boldsymbol{k}'_{\mathrm{e}}, \mu'_{\mathrm{e}}; \boldsymbol{k}'_{\mathrm{C}}, \mu'_j; \boldsymbol{k}'_{\gamma}, \mu'_{\gamma} | \hat{\mathcal{L}}^{\mathrm{C}}_{\mathrm{int}}(0) | \boldsymbol{k}_{\mathrm{e}}, \mu_{\mathrm{e}}; \boldsymbol{k}_{\mathrm{C}}, \mu_j \rangle \\
&\quad = \quad \frac{(-1)(2\pi)^6}{\sqrt{M'^3_{\mathrm{eC}} M^3_{\mathrm{eC}\gamma}}} V^0 \delta^3(\boldsymbol{V} - \boldsymbol{V}') \\
&\qquad\qquad \times \Big[\,|\,\mathrm{e}\,|\, Q_{\mathrm{e}}\, \bar{u}_{\mu'_{\mathrm{e}}}(\boldsymbol{k}'_{\mathrm{e}}) \gamma_{\nu} u_{\mu_{\mathrm{e}}}(\boldsymbol{k}_{\mathrm{e}})\, \epsilon^{\nu}_{\mu'_{\gamma}}(\boldsymbol{k}'_{\gamma})\, \delta_{\mu_j \mu'_j} 2k^0_{\mathrm{C}} \delta^3(\boldsymbol{k}'_{\mathrm{C}} - \boldsymbol{k}_{\mathrm{C}}) \\
&\qquad\qquad\quad + J_{\mathrm{C}\nu}(\boldsymbol{k}'_{\mathrm{C}}, \mu'_j; \boldsymbol{k}_{\mathrm{C}}, \mu_j; K_{\mathrm{e}})\, \epsilon^{\nu}_{\mu'_{\gamma}}(\boldsymbol{k}'_{\gamma})\, \delta_{\mu_{\mathrm{e}} \mu'_{\mathrm{e}}} 2k^0_{\mathrm{e}} \delta^3(\boldsymbol{k}'_{e} - \boldsymbol{k}_{\mathrm{e}}) \Big]\,.
\end{aligned} \tag{3.79}$$

---

[4] The four-momentum transfer squared Q_i^2 on the constituent should not be confused with the constituents charge (squared), but the distinction should be clear from the context.

Here $J^\mu_{\rm C}(\boldsymbol{k}'_{\rm C},\mu'_j;\boldsymbol{k}_{\rm C},\mu_j;K_{\rm e})$ is the bound-state current. It is the most general current that one can write down for a bound state with spin j and may contain phenomenological form factors that account for the substructure of the bound state. Beside the incoming and outgoing bound-state momenta and spins we have also written, as a further dependence, the sum of the incoming and outgoing electron momenta $K^\mu_{\rm e} := k^\mu_{\rm e} + k'^\mu_{\rm e}$ into the argument of the current. The latter dependence can be understood as an effect of the violation of cluster separability in the Bakamjian-Thomas framework, which has been already discussed in Sec. 3.4.4. As a consequence, the physical properties of the bound state are not independent of the electron. In particular, as we will see, the bound-state current contains, so-called, *unphysical* contributions that exhibit a dependence on $K_{\rm e}$. Finding an explicit form of $J^\mu_{\rm C}(\boldsymbol{k}'_{\rm C},\mu'_j;\boldsymbol{k}_{\rm C},\mu_j;K_{\rm e})$ in terms of bound-state wave functions and constituent currents and investigating its Lorentz structure is one of the central objectives of this work.

Covariance Properties

At first glance it might seem that the currents for the electron $\bar{u}_{\mu'_{\rm e}}(\boldsymbol{k}'_{\rm e})\gamma^\mu u_{\mu_{\rm e}}(\boldsymbol{k}_{\rm e})$, for the constituents $J^\mu_i(\boldsymbol{k}'_i,\mu'_i;\boldsymbol{k}_i,\mu_i)$ and for the bound-state $J^\mu_{\rm C}(\boldsymbol{k}'_{\rm C},\mu'_j;\boldsymbol{k}_{\rm C},\mu_j;K_{\rm e})$ defined in Eqs. (3.72) and (3.79) transform like four-vectors under Lorentz transformations. This is, however, not the case due to the center-of-mass momenta of the electron-bound-state(-photon) system that appear in the currents. The effect of a Lorentz transformation on such center-of-mass momenta is a Wigner rotation, which can be seen from the transformation properties of velocity states, Eq. (2.73). In order to investigate the transformation properties of the currents we look at velocity-state matrix elements of a Lorentz transformed vertex operator $\hat{\hat{K}}^\dagger = \hat{U}(\underline{\Lambda})\hat{K}^\dagger\hat{U}^\dagger(\underline{\Lambda})$ (using the short-hand notation $R^{(\prime)}_{\rm W_c} \equiv R^{(\prime)}_{\rm W_c}(V^{(\prime)},\Lambda)$):

$$\begin{aligned}
&\langle V';\boldsymbol{k}'_{\rm e},\mu'_{\rm e};\boldsymbol{k}'_1,\mu'_1;\boldsymbol{k}'_2,\mu'_2;\boldsymbol{k}'_\gamma,\mu'_\gamma|\hat{U}(\underline{\Lambda})\hat{K}\hat{U}^\dagger(\underline{\Lambda})|V;\boldsymbol{k}_{\rm e},\mu_{\rm e};\boldsymbol{k}_1,\mu_1;\boldsymbol{k}_2,\mu_2\rangle\\
&= \quad \langle \Lambda V';\boldsymbol{R}'_{\rm W_c}k'_{\rm e},\bar{\mu}'_{\rm e};\boldsymbol{R}'_{\rm W_c}k'_1,\bar{\mu}'_1;\boldsymbol{R}'_{\rm W_c}k'_2,\bar{\mu}'_2;\boldsymbol{R}'_{\rm W_c}k'_\gamma,\bar{\mu}'_\gamma|\\
&\qquad \times\hat{K}|\Lambda V;\boldsymbol{R}_{\rm W_c}k_{\rm e},\bar{\mu}_{\rm e};\boldsymbol{R}_{\rm W_c}k_1,\bar{\mu}_1;\boldsymbol{R}_{\rm W_c}k_2,\bar{\mu}_2\rangle D^{\frac{1}{2}*}_{\bar{\mu}'_{\rm e}\mu'_{\rm e}}(\underline{R}'_{\rm W_c})D^{\frac{1}{2}*}_{\bar{\mu}'_1\mu'_1}(\underline{R}'_{\rm W_c})\\
&\qquad \times D^{\frac{1}{2}*}_{\bar{\mu}'_2\mu'_2}(\underline{R}'_{\rm W_c})R_{\rm W_h}\left(k'_\gamma,R_{\rm W_c}\right)_{\bar{\mu}'_\gamma\mu'_\gamma}D^{\frac{1}{2}}_{\bar{\mu}_{\rm e}\mu_{\rm e}}(\underline{R}_{\rm W_c})D^{\frac{1}{2}}_{\bar{\mu}_1\mu_1}(\underline{R}_{\rm W_c})D^{\frac{1}{2}}_{\bar{\mu}_2\mu_2}(\underline{R}_{\rm W_c})\\
&= \quad \frac{(-1)(2\pi)^9}{\sqrt{M'^3_{\rm e12}M^3_{\rm e12\gamma}}}V^0\delta^3(\boldsymbol{V}-\boldsymbol{V}')\epsilon^\nu_{\bar{\mu}'_\gamma}(\boldsymbol{R}_{\rm W_c}k'_\gamma)R_{\rm W_h}\left(k'_\gamma,R_{\rm W_c}\right)_{\bar{\mu}'_\gamma\mu'_\gamma}\\
&\qquad \times\Big[\,|\,{\rm e}\,|\,Q_{\rm e}\,\bar{u}_{\bar{\mu}'_{\rm e}}(\boldsymbol{R}_{\rm W_c}k'_{\rm e})\gamma_\nu u_{\bar{\mu}_{\rm e}}(\boldsymbol{R}_{\rm W_c}k_{\rm e})D^{\frac{1}{2}*}_{\bar{\mu}'_{\rm e}\mu'_{\rm e}}(\underline{R}_{\rm W_c})D^{\frac{1}{2}}_{\bar{\mu}_{\rm e}\mu_{\rm e}}(\underline{R}_{\rm W_c})\\
&\qquad\quad \times\delta_{\mu_1\mu'_1}2k^0_1\delta^3(\boldsymbol{k}'_1-\boldsymbol{k}_1)\,\delta_{\mu_2\mu'_2}2k^0_2\delta^3(\boldsymbol{k}'_2-\boldsymbol{k}_2)\\
&\qquad\quad + J_{1\nu}(\boldsymbol{R}_{\rm W_c}k'_1,\bar{\mu}'_1;\boldsymbol{R}_{\rm W_c}k_1,\bar{\mu}_1)D^{\frac{1}{2}*}_{\bar{\mu}'_1\mu'_1}(\underline{R}_{\rm W_c})D^{\frac{1}{2}}_{\bar{\mu}_1\mu_1}(\underline{R}_{\rm W_c})\\
&\qquad\quad \times\delta_{\mu_{\rm e}\mu'_{\rm e}}2k^0_{\rm e}\delta^3(\boldsymbol{k}'_e-\boldsymbol{k}_e)\delta_{\mu_2\mu'_2}2k^0_2\delta^3(\boldsymbol{k}'_2-\boldsymbol{k}_2)\\
&\qquad\quad + J_{2\nu}(\boldsymbol{R}_{\rm W_c}k'_2,\bar{\mu}'_2;\boldsymbol{R}_{\rm W_c}k_2,\bar{\mu}_2)D^{\frac{1}{2}*}_{\bar{\mu}'_2\mu'_2}(\underline{R}_{\rm W_c})D^{\frac{1}{2}}_{\bar{\mu}_2\mu_2}(\underline{R}_{\rm W_c})\\
&\qquad\quad \times\delta_{\mu_{\rm e}\mu'_{\rm e}}2k^0_{\rm e}\delta^3(\boldsymbol{k}'_e-\boldsymbol{k}_e)\,\delta_{\mu_1\mu'_1}2k^0_1\delta^3(\boldsymbol{k}'_1-\boldsymbol{k}_1)\Big]\;. \qquad (3.80)
\end{aligned}$$

From the covariant transformation property of the polarization vectors, Eq. (B.24), we find

$$\epsilon^{\mu}_{\mu'_\gamma}(\boldsymbol{k}'_\gamma) \xrightarrow{\mathit{\Lambda}} \epsilon^{\nu}_{\bar{\mu}'_\gamma}(\boldsymbol{R}_{\mathrm{W_c}} k'_\gamma) = R_{\mathrm{W_c}}(V, \underline{\mathit{\Lambda}})^{\mu}{}_{\nu} \epsilon^{\nu}_{\mu'_\gamma}(\boldsymbol{k}'_\gamma) R^{-1}_{\mathrm{W_h}}\left(k'_\gamma, R_{\mathrm{W_c}}\right)_{\mu'_\gamma \bar{\mu}'_\gamma} . \tag{3.81}$$

Demanding Lorentz invariance of the vertex by comparing Eq. (3.80) with Eq. (3.71) we find the transformation properties of the currents under Lorentz transformations:

$$\begin{aligned} J^{\mu}_i(\boldsymbol{k}'_i, \mu'_i; \boldsymbol{k}_i, \mu_i) &\xrightarrow{\mathit{\Lambda}} J^{\mu}_i(\boldsymbol{R}_{\mathrm{W_c}} k'_i, \bar{\mu}'_i; \boldsymbol{R}_{\mathrm{W_c}} k_i, \bar{\mu}_i) \\ &= R_{\mathrm{W_c}}(V, \mathit{\Lambda})^{\mu}{}_{\nu} J^{\nu}_i(\boldsymbol{k}'_i, \mu'_i; \boldsymbol{k}_i, \mu_i) D^{j_i *}_{\mu'_i \bar{\mu}'_i}[\underline{R}^{-1}_{\mathrm{W_c}}(V, \mathit{\Lambda})] D^{j_i}_{\mu_i \bar{\mu}_i}[\underline{R}^{-1}_{\mathrm{W_c}}(V, \mathit{\Lambda})] \end{aligned} \tag{3.82}$$

with $i = \mathrm{e, q, N}$. For the bound-state current $J^{\mu}_{\mathrm{C}}(\boldsymbol{k}'_{\mathrm{C}}, \mu'_j; \boldsymbol{k}_{\mathrm{C}}, \mu_j; K_{\mathrm{e}})$ one finds the same transformation properties as in Eq. (3.82). We see that our currents do not behave like four-vectors under Lorentz transformations. Instead, they transform by a Wigner rotation $R_{\mathrm{W_c}}(V, \mathit{\Lambda})$. Currents with the correct covariance properties, however, are obtained by going back to the physical particle momenta $p_i^{(\prime)}$ and spin projections $\sigma_i^{(\prime)}$ of Eq. (2.60) by means of a canonical boost with velocity $\boldsymbol{V}$ (cf. Eq. (2.67)) and a Wigner rotation $R^{-1}_{\mathrm{W_c}}(w_i^{(\prime)}, B_{\mathrm{c}}(\boldsymbol{V}))$, respectively. Such *covariant currents* are defined by [BSFK09]

$$\begin{aligned} J^{\mu}_i(\boldsymbol{p}'_i, \sigma'_i; \boldsymbol{p}_i, \sigma_i) \quad :=& \quad B_{\mathrm{c}}(\boldsymbol{V})^{\mu}{}_{\nu} J^{\nu}_i(\boldsymbol{k}'_i, \mu'_i; \boldsymbol{k}_i, \mu_i) \\ & \times D^{j_i *}_{\mu'_i \sigma'_i}[\underline{R}^{-1}_{\mathrm{W_c}}(w'_i, B_{\mathrm{c}}(\boldsymbol{V}))] D^{j_i}_{\mu_i \sigma_i}[\underline{R}^{-1}_{\mathrm{W_c}}(w_i, B_{\mathrm{c}}(\boldsymbol{V}))] \end{aligned} \tag{3.83}$$

with $i = \mathrm{e, q, N}$. It is checked in App. D.2.1 that these currents exhibit the correct covariance properties under Lorentz transformations. Similarly, the bound-state current $J^{\mu}_{\mathrm{C}}(\boldsymbol{p}'_{\mathrm{C}}, \sigma'_j; \boldsymbol{p}_{\mathrm{C}}, \sigma_j; P_{\mathrm{e}})$ with $P_{\mathrm{e}} = p_{\mathrm{e}} + p'_{\mathrm{e}}$ is obtained according to the prescription of Eq. (3.83).[5]

---

[5] The term 'physical current' for $J^{\mu}_{\mathrm{C}}(\boldsymbol{p}'_{\mathrm{C}}, \sigma'_j; \boldsymbol{p}_{\mathrm{C}}, \sigma_j; P_{\mathrm{e}})$ is avoided due to the *unphysical* contributions proportional to P_{e} which may occur in the expression for this current. Therefore, we rather speak in this context of *covariant currents*. We use the same notation both for the covariant current $J^{\mu}_{\mathrm{C}}(\boldsymbol{p}'_{\mathrm{C}}, \sigma'_j; \boldsymbol{p}_{\mathrm{C}}, \sigma_j; P_{\mathrm{e}})$ and for the current $J^{\mu}_{\mathrm{C}}(\boldsymbol{k}'_{\mathrm{C}}, \mu'_j; \boldsymbol{k}_{\mathrm{C}}, \mu_j; K_{\mathrm{e}})$. The difference is indicated by the arguments.

Chapter 4

Relativistic Coupled-Channel Problem

4.1 Introduction

In this chapter we look at elastic electron-bound-state scattering in the center-of-momentum frame. This process is treated in the one-photon-approximation as a coupled-channel problem for a Bakamjian-Thomas-type mass operator. The corresponding system of coupled equations can be reduced to an eigenvalue problem for the elastic channel with a one-photon-exchange optical potential. 'On-shell' matrix elements of this optical potential in the velocity state basis are sufficient for the identification and extraction of the electromagnetic bound-state current. Corresponding analytical expressions in terms of bound-state wave functions and constituent currents will be derived. The following formalism can also be found in Ref. [BSFK09] for the particular case of the bound state being a pseudoscalar meson.

4.2 Electron-Bound-State Scattering

4.2.1 Coupled-Channel Problem

The kinematic group of the point form is the Lorentz group which makes a manifest Lorentz covariant formulation feasible. It is easy in the point form to obtain a relativistic generalization of the Schrödinger equation. This is achieved by simply replacing the non-relativistic Hamiltonian, i.e. the energy operator, by the four-momentum operator, whose components contain all interactions of the system. The resulting dynamical equations to be solved are given by the eigenvalue problem for the four-momentum operator [Kli03a]:

$$\hat{P}^{\mu}|\Psi\rangle = P^{\mu}|\Psi\rangle \,. \tag{4.1}$$

We have already pointed out in Sec. 3.3 that a point-form Bakamjian-Thomas construction results in a total four-momentum operator that is the product of the free four-velocity operator times the total mass operator, cf. Eq. (3.5). The latter contains all information about the dynamics of the system. As a consequence it suffices to study the eigenvalue problem for the mass operator. Therefore Eq. (4.1) can be reduced to

$$\hat{M}|\Psi\rangle = M|\Psi\rangle\,. \tag{4.2}$$

Our aim is to construct a Bakamjian-Thomas type mass operator $\hat{M}$ that describes photon exchange in such a way that retardation effects are fully taken into account. This can be achieved within a coupled-channel framework that allows for the creation and annihilation of a photon by means of the vertex operators defined in the previous chapter. To this end we treat the electromagnetic scattering of an electron by a bound two-body system as a two-channel problem for an appropriately defined Bakamjian-Thomas type mass operator. Such a mass operator acts on a Hilbert space that is the direct sum of the 12e and 12eγ Hilbert spaces. It can be written as a (2×2)-matrix operator [Kli03a]

$$\hat{M} := \hat{M}_{\mathrm{Ce}(\gamma)} + \hat{M}_{\mathrm{int}} = \begin{pmatrix} \hat{M}_{\mathrm{Ce}} & 0 \\ 0 & \hat{M}_{\mathrm{Ce}\gamma} \end{pmatrix} + \begin{pmatrix} 0 & \hat{K} \\ \hat{K}^\dagger & 0 \end{pmatrix}\,. \tag{4.3}$$

The diagonal elements of this mass operator, $\hat{M}_{\mathrm{Ce}}$ and $\hat{M}_{\mathrm{Ce}\gamma}$ of Eqs. (3.20) and (3.34), respectively, are the invariant mass operators of the uncoupled Ce- and Ceγ-systems. They may contain instantaneous two-body interactions between the constituents 1 and 2 (in the way introduced in Sec. 3.4). The off-diagonal terms $\hat{K}^\dagger$ and $\hat{K}$ are the vertex operators defined by Eq. (3.71) and they account for the creation and annihilation of the photon at the electron and the constituents. In this way they couple the 12e Hilbert space to the 12eγ Hilbert space. The mass operator of Eq. (4.3) is of point-form Bakamjian-Thomas type (cf. Eq. (3.6)) since it is defined to commute with $\hat{V}^\mu$ due to the delta functions in Eqs. (3.17) and (3.71). Decomposing an arbitrary mass eigenstate of the system $|\Psi\rangle$ into components belonging to the 2 channels 12e and 12eγ,

$$|\Psi\rangle := \begin{pmatrix} |\Psi_{\mathrm{Ce}}\rangle \\ |\Psi_{\mathrm{Ce}\gamma}\rangle \end{pmatrix}, \tag{4.4}$$

and inserting the definitions (4.3) and (4.4) into the eigenvalue equation (4.2) we have

$$\begin{pmatrix} \hat{M}_{\mathrm{Ce}} & \hat{K} \\ \hat{K}^\dagger & \hat{M}_{\mathrm{Ce}\gamma} \end{pmatrix} \begin{pmatrix} |\Psi_{\mathrm{Ce}}\rangle \\ |\Psi_{\mathrm{Ce}\gamma}\rangle \end{pmatrix} = M \begin{pmatrix} |\Psi_{\mathrm{Ce}}\rangle \\ |\Psi_{\mathrm{Ce}\gamma}\rangle \end{pmatrix}. \tag{4.5}$$

This is a linear system of 2 coupled equations for the respective components:

$$\hat{M}_{\mathrm{Ce}}|\Psi_{\mathrm{Ce}}\rangle + \hat{K}|\Psi_{\mathrm{Ce}\gamma}\rangle = M|\Psi_{\mathrm{Ce}}\rangle\,, \tag{4.6}$$

$$\hat{K}^\dagger|\Psi_{\mathrm{Ce}}\rangle + \hat{M}_{\mathrm{Ce}\gamma}|\Psi_{\mathrm{Ce}\gamma}\rangle = M|\Psi_{\mathrm{Ce}\gamma}\rangle\,. \tag{4.7}$$

4.2.2 One-Photon-Exchange Optical Potential

Constituents

For our further purposes it is useful to apply a Feshbach reduction to Eqs. (4.6) and (4.7) which means to solve the second equation for $|\Psi_{\mathrm{Ce}\gamma}\rangle$ and insert the resulting expression into the first one to end up with an equation for $|\Psi_{\mathrm{Ce}}\rangle$:

$$\left(\hat{M}_{\mathrm{Ce}} - M\right)|\Psi_{\mathrm{Ce}}\rangle = \underbrace{\hat{K}\left(\hat{M}_{\mathrm{eC}\gamma} - M\right)^{-1}\hat{K}^\dagger}_{=:\hat{V}_{\mathrm{opt}}(M)}|\Psi_{\mathrm{Ce}}\rangle\,. \tag{4.8}$$

The right-hand side of this equation describes the action of the one-photon-exchange on the state $|\Psi_{\mathrm{Ce}}\rangle$. This equation has the structure of an eigenvalue equation, but with the mass eigenvalue M also appearing in the optical potential $\hat{V}_{\mathrm{opt}}(M)$. $\hat{V}_{\mathrm{opt}}(M)$ consists of all possibilities to exchange the photon between the electron and the constituents. It also includes loop contributions, i.e. absorption by the emitting particle. $(M - \hat{M}_{\mathrm{Ce}\gamma})^{-1}$ describes the propagation of the Ceγ intermediate state and is thus responsible for retardation effects.

Bound State

On the bound-state level, where the structure of the bound state is not resolved in terms of constituents, the corresponding one-photon-exchange optical potential is simply obtained by replacing $\hat{K}$ with $\hat{K}^{\mathrm{C}}$ of Eq. (3.79) in $\hat{V}_{\mathrm{opt}}(M)$:

$$\hat{V}^{\mathrm{C}}_{\mathrm{opt}}(M) := \hat{K}^{\mathrm{C}}\left(\hat{M}_{\mathrm{Ce}\gamma} - M\right)^{-1}\hat{K}^{\mathrm{C}\dagger}\,, \tag{4.9}$$

with $\hat{V}^{\mathrm{C}}_{\mathrm{opt}}(M)$ acting now on a two-particle Ce Hilbert space.

4.3 Calculation of the Bound-State Current

4.3.1 Matrix Elements of the Optical Potential

Our objective of this section is to derive an expression for the bound-state current $J^{\mu}_{\mathrm{C}}(\boldsymbol{k}'_{\mathrm{C}}, \mu'_j; \boldsymbol{k}_{\mathrm{C}}, \mu_j; K_{\mathrm{e}})$ in terms of bound-state wave functions and constituent currents. To this end we consider matrix elements of the optical potential $\hat{V}_{\mathrm{opt}}(M)$ of Eq. (4.8) between velocity states of the electron-bound-state system. The electromagnetic current of a bound state is usually extracted from the elastic electron-bound-state scattering amplitude calculated in the one-photon-exchange approximation. This means that we can restrict our considerations to 'on-shell' (os) matrix elements of $\hat{V}_{\mathrm{opt}}(M)$ for which the total invariant mass of the incoming and outgoing electron and bound state has to be the same, i.e.

$$M = k^0_{\mathrm{e}} + k^0_{\mathrm{C}} = k'^0_{\mathrm{e}} + k'^0_{\mathrm{C}} \tag{4.10}$$

since

$$k^0_{\mathrm{e}} = k'^0_{\mathrm{e}} \quad \text{and} \quad k^0_{\mathrm{C}} = k'^0_{\mathrm{C}}\,. \tag{4.11}$$

Note that the velocity-state representation is associated with center-of-mass kinematics, cf. Eq. (2.68).

We start our calculation by looking at on-shell matrix elements of the optical potential between clustered electron-bound-state velocity states of Sec. 3.4.2:[1]

$$\begin{aligned}
&\langle \underline{V}'; \underline{\boldsymbol{k}}'_{\mathrm{e}}, \underline{\mu}'_{\mathrm{e}}; \underline{\boldsymbol{k}}'_{12}, n, j, \mu'_j|\, \hat{V}_{\mathrm{opt}}(M)|\, \underline{V}; \underline{\boldsymbol{k}}_{\mathrm{e}}, \underline{\mu}_{e}; \underline{\boldsymbol{k}}_{12}, n, j, \mu_j\rangle_{\mathrm{os}} \\
&\quad= \langle \underline{V}'; \underline{\boldsymbol{k}}'_{\mathrm{e}}, \underline{\mu}'_{\mathrm{e}}; \underline{\boldsymbol{k}}'_{12}, n, j, \mu'_j|\, \hat{K}\left(\hat{M}_{\mathrm{eC}\gamma} - M\right)^{-1}\hat{K}^{\dagger} \\
&\qquad \times|\, \underline{V}; \underline{\boldsymbol{k}}_{\mathrm{e}}, \underline{\mu}_{\mathrm{e}}; \underline{\boldsymbol{k}}_{12}, n, j, \mu_j\rangle_{\mathrm{os}}\,.
\end{aligned} \tag{4.12}$$

---

[1] Here we introduce the 'underlining' of spins, momenta and velocities in order to have a further mean (beside multiple primes) for distinguishing quantum numbers in clustered from those in free velocity states. This underline should not be confused with the underline denoting elements of the SL(2, $\mathbb{C}$), but the distinction should be clear from the context.

The first step towards an evaluation of Eq. (4.12) is a multiple insertion of the completeness relations for free and clustered velocity states, cf. Eqs. (2.77) and (3.37), at the appropriate places on the right-hand side of Eq. (4.12):

$$\begin{aligned}\langle \underline{V}'; \underline{\boldsymbol{k}}'_{\mathrm{e}}, \underline{\mu}'_{\mathrm{e}}; \underline{\boldsymbol{k}}'_{12}, n, j, \mu'_j |\, \hat{1}'_{12\mathrm{e}}\, \hat{K}\, \hat{1}'''_{12\mathrm{e}\gamma} \left(\hat{M}_{\mathrm{eC}\gamma} - M \right)^{-1} \hat{1}''_{\mathrm{Ce}\gamma} \\ \times \hat{1}''_{12\mathrm{e}\gamma}\, \hat{K}^\dagger\, \hat{1}_{12\mathrm{e}} \,|\, \underline{V}; \underline{\boldsymbol{k}}_{\mathrm{e}}, \underline{\mu}_{\mathrm{e}}; \underline{\boldsymbol{k}}_{12}, n, j, \mu_j \rangle_{\mathrm{os}} \,. \qquad (4.13)\end{aligned}$$

Next we use the orthogonality relations for the free and clustered velocity states, Eqs. (2.78) and (3.36), respectively, together with the expressions for the matrix elements of the vertex operators, Eq. (3.71), and the definitions of the wave functions, Eqs. (3.23) and (3.35). Then the necessary integrations and sums can be done by means of the appropriate Dirac and Kronecker deltas, respectively. In the rather lengthy calculation, which is presented in detail in App. E, we neglect the 5 self-energy contributions in which the photon is emitted and absorbed by the same particle.[2] The remaining 4 time-ordered contributions can be combined to 2 covariant contributions corresponding to the photon exchange between the electron and the two constituents. The result has the structure of a contraction of the electron current with the sum of 2 integrals (involving the wave functions and the constituent currents) multiplied with the covariant photon propagator:

$$\begin{aligned}&\langle \underline{V}'; \underline{\boldsymbol{k}}'_{\mathrm{e}}, \underline{\mu}'_{\mathrm{e}}; \underline{\boldsymbol{k}}'_{12}, n, j, \mu'_j |\, \hat{V}_{\mathrm{opt}}(M) \,|\, \underline{V}; \underline{\boldsymbol{k}}_{\mathrm{e}}, \underline{\mu}_{e}; \underline{\boldsymbol{k}}_{12}, n, j, \mu_j \rangle_{\mathrm{os}} \\ &= \quad (2\pi)^3 \underline{V}^0 \delta^3(\underline{\boldsymbol{V}} - \underline{\boldsymbol{V}}') \sqrt{\frac{2k'^0_{\mathrm{C}}}{(k'^0_{\mathrm{C}} + \underline{k}'^0_{\mathrm{e}})^3}} \sqrt{\frac{2k^0_{\mathrm{C}}}{(k^0_{\mathrm{C}} + \underline{k}^0_{\mathrm{e}})^3}} \\ &\qquad \times \sum_{\mu'_1 \mu'_2} \Bigg[\int \frac{\mathrm{d}^3 k'_1}{2k'^0_1} \frac{1}{2k'^0_2} \frac{1}{2k^0_1} \sqrt{\frac{2\tilde{k}'^0_1 2\tilde{k}'^0_2}{2(\tilde{k}'^0_1 + \tilde{k}'^0_2)}} \sqrt{\frac{2\tilde{k}^0_1 2\tilde{k}^0_2}{2(\tilde{k}^0_1 + \tilde{k}^0_2)}} \sqrt{2k'^0_{12}} \sqrt{2k^0_{12}} \\ &\qquad\qquad \times \sum_{\mu_1} \Psi^*_{nj\mu'_j \mu'_1 \mu'_2}(\tilde{\boldsymbol{k}}') \Psi_{nj\mu_j \mu_1 \mu'_2}(\tilde{\boldsymbol{k}}) J_{1\nu}(\boldsymbol{k}'_1, \mu'_1; \boldsymbol{k}_1, \mu_1) \\ &\qquad\quad + \int \frac{\mathrm{d}^3 k'_2}{2k'^0_2} \frac{1}{2k'^0_1} \frac{1}{2k^0_2} \sqrt{\frac{2\tilde{k}'^0_1 2\tilde{k}'^0_2}{2(\tilde{k}'^0_1 + \tilde{k}'^0_2)}} \sqrt{\frac{2\tilde{k}^0_1 2\tilde{k}^0_2}{2(\tilde{k}^0_1 + \tilde{k}^0_2)}} \sqrt{2k'^0_{12}} \sqrt{2k^0_{12}} \\ &\qquad\qquad \times \sum_{\mu_2} \Psi^*_{nj\mu'_j \mu'_1 \mu'_2}(\tilde{\boldsymbol{k}}') \Psi_{nj\mu_j \mu'_1 \mu_2}(\tilde{\boldsymbol{k}}) J_{2\nu}(\boldsymbol{k}'_2, \mu'_2; \boldsymbol{k}_2, \mu_2) \Bigg] \\ &\qquad \times \frac{(-\mathrm{g}^{\mu\nu})}{Q^2} \,|\,\mathrm{e}\,|\, Q_{\mathrm{e}}\, \bar{u}_{\underline{\mu}'_{\mathrm{e}}}(\boldsymbol{k}'_{\mathrm{e}}) \gamma_\mu u_{\underline{\mu}_{\mathrm{e}}}(\boldsymbol{k}_e) \,. \qquad (4.14)\end{aligned}$$

A diagrammatic representation of these contributions is depicted in Fig. 4.1. Here the blobs that connect the c_1 and c_2 lines symbolize integrals over wave functions of the incoming and outgoing bound state. The denominator of the covariant photon propagator, which includes both time orderings, is given by $-q_\mu q^\mu = Q^2$ with $q^\mu = k'^\mu_{\mathrm{C}} - k^\mu_{\mathrm{C}}$ being the four-momentum transfer between electron and bound state.[3] Momenta with and without prime are related by $\boldsymbol{k}'_i = \boldsymbol{k}_i + \boldsymbol{q} = \boldsymbol{k}_i + \boldsymbol{k}_\gamma$ with $i = 1$, 2 and $\boldsymbol{k}'_{\mathrm{e}} = \boldsymbol{k}_{\mathrm{e}} - \boldsymbol{k}_\gamma$. This means that we have

---

[2] Photon exchange between particles 1 and 2 is also excluded as it is a self-energy contribution to the bound state.

[3] Note that $\boldsymbol{q} = \boldsymbol{k}_\gamma$, but $q^0 \neq k^0_\gamma = |\boldsymbol{k}_\gamma|$.

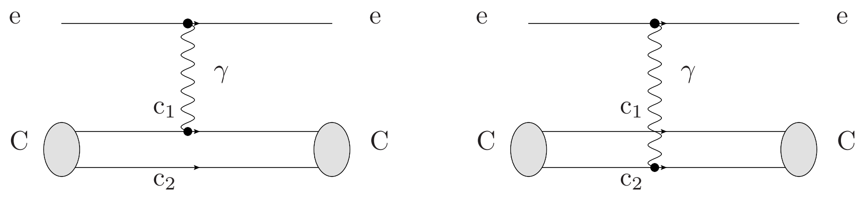

Figure 4.1: The diagrammatic representation of the 2 covariant contributions to the one-photon-optical potential corresponding to the 2 terms in Eq. (4.14).

three-momentum conservation at the electromagnetic vertices, a property which one would not expect in point-form quantum mechanics. Here it results from the velocity-state representation, in particular the associated center-of-mass kinematics and the spectator conditions for the inactive particles. The energy is, however, not conserved at the vertices. For the physical momenta, i.e. the center-of-mass momenta boosted by $B_{\mathrm{c}}(\boldsymbol{V})$, none of the four-momentum components is, in general (if $\boldsymbol{V} \neq 0$), conserved at the electromagnetic vertices.[4]

4.3.2 Matrix Elements of the Optical Potential on the Bound-State Level

In a similar way as in the previous section on the constituent level we can also calculate on-shell velocity-state matrix elements of the optical potential $\hat{V}^{\mathrm{C}}_{\mathrm{opt}}(M)$ given by Eq. (4.9). We work on the bound-state level which means that the structure of the bound state is not resolved in terms of constituents. The purpose of this calculation is the identification of the bound-state current from Eq. (4.14). In particular, it serves for the identification of the kinematical factors belonging to the current, which stand in front of the integral of Eq. (4.14). The explicit calculation will not be demonstrated here, instead we refer to the thorough derivation in Ref. [Fuc07]. It is briefly summarized as follows: one starts with the insertion of a velocity-state completeness relation at the appropriate place of matrix elements of $\hat{V}^{\mathrm{C}}_{\mathrm{opt}}(M)$. Then one uses the matrix elements of the vertex operators between velocity states, Eq. (3.79), in order to carry out the necessary integrals and sums by means of the corresponding Dirac and Kronecker deltas, respectively. If self-energy contributions are again neglected the optical potential consists of 2 terms corresponding to the 2 possible time orderings. Restricting ourselves to on-shell matrix elements, cf. Eq. (4.10), we can combine the 2 time orderings to the covariant photon propagator, cf. Eq. (E.12). The final result is then given by [Fuc07, BSFK09]

$$\begin{aligned}
&\langle V'; \boldsymbol{k}'_{\mathrm{e}}, \mu'_{\mathrm{e}}; \boldsymbol{k}'_{12}, \mu'_j |\, \hat{V}^{\mathrm{C}}_{\mathrm{opt}}(M) \,| V; \boldsymbol{k}_{\mathrm{e}}, \mu_{\mathrm{e}}; \boldsymbol{k}_{12}, \mu_j \rangle_{\mathrm{os}} \\
&\quad = \; (2\pi)^3 V^0 \delta^3(\boldsymbol{V} - \boldsymbol{V}') \frac{1}{\sqrt{(k'^0_{\mathrm{e}} + k'^0_{\mathrm{C}})^3}} \frac{1}{\sqrt{(k^0_{\mathrm{e}} + k^0_{\mathrm{C}})^3}} \\
&\qquad \times |\,\mathrm{e}\,|\, Q_{\mathrm{e}} \bar{u}_{\mu'_{\mathrm{e}}}(\boldsymbol{k}'_{\mathrm{e}}) \gamma_\mu u_{\mu_{\mathrm{e}}}(\boldsymbol{k}_e) \frac{(-\mathrm{g}^{\mu\nu})}{Q^2} J_{\mathrm{C}\nu}(\boldsymbol{k}'_{\mathrm{C}}, \mu'_j; \boldsymbol{k}_{\mathrm{C}}, \mu_j; K_{\mathrm{e}}) \,. \qquad (4.15)
\end{aligned}$$

---

[4] Note that boosts mix spatial and temporal components.

The expression on the right-hand side reveals that on-shell matrix elements of the optical potential can be expressed as a contraction of the electromagnetic electron current $|\,\mathrm{e}\,|\,Q_\mathrm{e}\bar{u}_{\mu_\mathrm{e}'}(\boldsymbol{k}_\mathrm{e}')\gamma_\mu u_{\mu_\mathrm{e}}$ with an electromagnetic bound-state current $J_{\mathrm{C}\nu}(\boldsymbol{k}_\mathrm{C}', \mu_j'; \boldsymbol{k}_\mathrm{C}, \mu_j; K_\mathrm{e})$ multiplied with the covariant photon propagator $-g^{\mu\nu}/Q^2$ (and a kinematical factor). Apart from the kinematical factor in front, the right-hand side of Eq. (4.15) corresponds to the familiar one-photon exchange amplitude for elastic electron-bound-state scattering (calculated in the electron-bound-state center-of-mass system).

It should be mentioned that, in general, the four-momentum transfer between incoming and outgoing (active) constituent $q_1^\mu := (k_1' - k_1)^\mu$ deviates from the four-momentum transfer between incoming and outgoing cluster $q^\mu := (k_\mathrm{C}' - k_\mathrm{C})^\mu$. This can be seen as follows: whereas the three-momentum transfers are the same on the bound-state and on the constituent level, i.e. $\boldsymbol{q} = \boldsymbol{q}_1$, the zero components differ, i.e. $q^0 \neq q_1^0$. Due to the center-of-mass kinematics associated with the velocity states $k_\mathrm{C}^0 = k_\mathrm{C}'^0$ and hence $q^0 = 0$. On the other hand it can be shown that

$$(k_1'^0)^2 = (k_1^0)^2 - 2\boldsymbol{q}\cdot\boldsymbol{k}_2' \quad \text{so that} \quad q_1^0 \neq 0\,. \tag{4.16}$$

Accordingly, not all of the four-momentum transferred to the cluster is also transferred to the active constituent.

4.3.3 Identifying the Bound-State Current

By comparison of Eq. (4.15) with Eq. (4.14) we can identify the bound-state current as

$$\begin{aligned}
&J_\mathrm{C}^\mu(\boldsymbol{k}_\mathrm{C}', \mu_j'; \boldsymbol{k}_\mathrm{C}, \mu_j; K_\mathrm{e}) \\
&\quad = \sqrt{2k_\mathrm{C}^0}\sqrt{2k_\mathrm{C}'^0}\sum_{\mu_1'\mu_2'}\Bigg[\int \frac{\mathrm{d}^3k_1'}{2k_1'^0}\frac{1}{2k_2'^0}\frac{1}{2k_1^0}\sqrt{\frac{2\tilde{k}_1'^0 2\tilde{k}_2'^0}{2(\tilde{k}_1'^0+\tilde{k}_2'^0)}}\sqrt{\frac{2\tilde{k}_1^0 2\tilde{k}_2^0}{2(\tilde{k}_1^0+\tilde{k}_2^0)}} \\
&\qquad\times\sqrt{2k_{12}'^0}\sqrt{2k_{12}^0}\sum_{\mu_1}\varPsi^*_{nj\mu_j'\mu_1'\mu_2'}(\tilde{\boldsymbol{k}}')\varPsi_{nj\mu_j\mu_1\mu_2'}(\tilde{\boldsymbol{k}})J_1^\mu(\boldsymbol{k}_1'\mu_1'; \boldsymbol{k}_1, \mu_1) \\
&\qquad+\int \frac{\mathrm{d}^3k_2'}{2k_2'^0}\frac{1}{2k_1'^0}\frac{1}{2k_2^0}\sqrt{\frac{2\tilde{k}_1'^0 2\tilde{k}_2'^0}{2(\tilde{k}_1'^0+\tilde{k}_2'^0)}}\sqrt{\frac{2\tilde{k}_1^0 2\tilde{k}_2^0}{2(\tilde{k}_1^0+\tilde{k}_2^0)}}\sqrt{2k_{12}'^0}\sqrt{2k_{12}^0} \\
&\qquad\times\sum_{\mu_2}\varPsi^*_{nj\mu_j'\mu_1'\mu_2'}(\tilde{\boldsymbol{k}}')\varPsi_{nj\mu_j\mu_1'\mu_2}(\tilde{\boldsymbol{k}})J_2^\mu(\boldsymbol{k}_2', \mu_2'; \boldsymbol{k}_2, \mu_2)\Bigg]\,.
\end{aligned} \tag{4.17}$$

Simplifications for Equal Mass and Spin of the Constituents

In the this work we restrict our considerations to bound systems consisting of 2 equal-mass equal-spin constituents. For the treatment of systems with unequal constituent masses within the present formalism, like heavy-light bound systems, we refer to Refs. [GRS10, GRS11]. According to our case, we assume the constituents to have equal masses, i.e. $m_1 = m_2 =: m$ and same spins, i.e. $j_1 = j_2 = \frac{1}{2}$, which simplifies the expression for the current, Eq. (4.17), even further. First we manipulate the second term of Eq. (4.17) by simply renaming momenta and spins (which are integrated and summed over). We make the replacements

$$k_1' \leftrightarrow k_2' \,, \quad k_1 \leftrightarrow k_2 \quad \text{and} \quad \mu_1' \leftrightarrow \mu_2' \,, \quad \mu_1 \leftrightarrow \mu_2 \,. \tag{4.18}$$

Consequently, using the symmetry of the Clebsch-Gordan coefficients, i.e. $C^{s\mu_s}_{j_1\mu_1 j_2\mu_2} = C^{s\mu_s}_{j_2\mu_2 j_1\mu_1}$, we can write Eq. (4.17) in a more compact form:

$$\begin{aligned} & J^\mu_{\mathrm{C}}(\boldsymbol{k}'_{\mathrm{C}}, \mu'_j; \boldsymbol{k}_{\mathrm{C}}, \mu_j; K_{\mathrm{e}}) \\ = \quad & \sqrt{2k^0_{\mathrm{C}}}\sqrt{2k'^0_{\mathrm{C}}} \sum_{\mu'_1\mu'_2\mu_1} \int \frac{\mathrm{d}^3k'_1}{2k'^0_1} \frac{1}{2k'^0_2} \frac{1}{2k^0_1} \sqrt{\frac{2\tilde{k}'^0_1 2\tilde{k}'^0_2}{2(\tilde{k}'^0_1 + \tilde{k}'^0_2)}} \sqrt{\frac{2\tilde{k}^0_1 2\tilde{k}^0_2}{2(\tilde{k}^0_1 + \tilde{k}^0_2)}} \\ & \times \sqrt{2k'^0_{12}}\sqrt{2k^0_{12}} \Psi^*_{nj\mu'_j\mu'_1\mu'_2}(\tilde{\boldsymbol{k}}') \Psi_{nj\mu_j\mu_1\mu'_2}(\tilde{\boldsymbol{k}}) \\ & \times \left[J^\mu_1(\boldsymbol{k}'_1, \mu'_1; \boldsymbol{k}_1, \mu_1) + J^\mu_2(\boldsymbol{k}'_1, \mu'_1; \boldsymbol{k}_1, \mu_1)\right] \,. \end{aligned} \tag{4.19}$$

A further simplification of this expression is achieved by going from the k'_1-integration to a $\tilde{k}'_1$-integration by means of the appropriate Jacobian, cf. Eq. (E.4). Note that for equal masses we have $\tilde{k}^0_1 = \tilde{k}^0_2 = m_{12}/2$ and $\tilde{k}'^0_1 = \tilde{k}'^0_2 = m'_{12}/2$. Moreover, it can be shown that the spinor product for anti-particles, $\bar{v}_{\mu_1}(\boldsymbol{k}_1)\gamma^\mu v_{\mu'_1}(\boldsymbol{k}'_1)$, can be replaced by the one for particles, $\bar{u}_{\mu'_1}(\boldsymbol{k}'_1)\gamma^\mu u_{\mu_1}(\boldsymbol{k}_1)$, cf. Eq. (B.11). Writing out the wave functions defined in Eq. (3.14) we can combine the Wigner D-functions for the inactive (spectator) constituent 2 by means of Eq. (C.5) due to the spectator condition $\boldsymbol{k}_2 = \boldsymbol{k}'_2$:

$$\underline{R}^{-1}_{\mathrm{W_c}}\left(\tilde{w}'_2, B_{\mathrm{c}}(\boldsymbol{w}'_{12})\right) \underline{R}_{\mathrm{W_c}}\left(\tilde{w}_2, B_{\mathrm{c}}(\boldsymbol{w}_{12})\right) = \underline{R}_{\mathrm{W_c}}\left(\tilde{w}_2, B^{-1}_{\mathrm{c}}(\boldsymbol{w}'_{12}) B_{\mathrm{c}}(\boldsymbol{w}_{12})\right) \,. \tag{4.20}$$

With these manipulations the expression for the bound-state current finally reads

$$\begin{aligned} & J^\mu_{\mathrm{C}}(\boldsymbol{k}'_{\mathrm{C}}, \mu'_j; \boldsymbol{k}_{\mathrm{C}}, \mu_j; K_{\mathrm{e}}) \\ = \quad & \sqrt{2k^0_{\mathrm{C}}}\sqrt{2k'^0_{\mathrm{C}}} \sum \int \frac{\mathrm{d}^3\tilde{k}'_1}{k^0_1} \sqrt{\frac{m_{12}}{m'_{12}}} \sqrt{\frac{k^0_{12}}{k'^0_{12}}} \\ & \times Y^*_{l'\mu'_l}(\hat{\tilde{\boldsymbol{k}}}') C^{s'\mu'_s *}_{\frac{1}{2}\tilde{\mu}'_1 \frac{1}{2}\tilde{\mu}'_2} C^{j\mu'_j *}_{l'\mu'_l s'\mu'_s} u^{j*}_{nl's'}(\tilde{k}') Y_{l\mu_l}(\hat{\tilde{\boldsymbol{k}}}) C^{s\mu_s}_{\frac{1}{2}\tilde{\mu}_1 \frac{1}{2}\tilde{\mu}_2} C^{j\mu_j}_{l\mu_l s\mu_s} u^j_{nls}(\tilde{k}) \\ & \times D^{\frac{1}{2}}_{\tilde{\mu}'_1\mu'_1}\left[\underline{R}^{-1}_{\mathrm{Wc}}\left(\tilde{w}'_1, B_{\mathrm{c}}(\boldsymbol{w}'_{12})\right)\right] D^{\frac{1}{2}}_{\mu_1\tilde{\mu}_1}\left[\underline{R}_{\mathrm{Wc}}\left(\tilde{w}_1, B_{\mathrm{c}}(\boldsymbol{w}_{12})\right)\right] \\ & \times D^{\frac{1}{2}}_{\tilde{\mu}'_2\tilde{\mu}_2}\left[\underline{R}_{\mathrm{Wc}}\left(\tilde{w}_2, B^{-1}_{\mathrm{c}}(\boldsymbol{w}'_{12}) B_{\mathrm{c}}(\boldsymbol{w}_{12})\right)\right] \\ & \times |\,\mathrm{e}\,|\, \bar{u}_{\mu'_1}(\boldsymbol{k}'_1)(\mathit{\Gamma}_1 + \mathit{\Gamma}_2)^\mu u_{\mu_1}(\boldsymbol{k}_1) \,. \end{aligned} \tag{4.21}$$

Here $\mathit{\Gamma}^\mu_i$ is the $\mathrm{c}_i\gamma\mathrm{c}_i$-vertex. It is given for point-like and non-point-like constituents like quarks and nucleons by the expressions

$$\mathit{\Gamma}^\mu_{\mathrm{q}} = Q_{\mathrm{q}}\gamma^\mu \quad \text{and} \quad \mathit{\Gamma}^\mu_{\mathrm{N}} = F^{\mathrm{N}}_1(Q^2_{\mathrm{N}})\gamma^\mu + F^{\mathrm{N}}_2(Q^2_{\mathrm{N}}) \frac{\mathrm{i}\, q_{\mathrm{N}\nu}\sigma^{\mu\nu}}{2m_{\mathrm{N}}} \,, \tag{4.22}$$

respectively.

4.4 Current Properties

In this section we investigate hermiticity, covariance and continuity properties of our bound-state current given by Eq. (4.21). The two former can be discussed without specifying the spin of the bound state. For the latter we consider the particular cases of a pseudoscalar and a vector bound state.

4.4.1 Hermiticity

Hermiticity of the current means that

$$\begin{aligned} J^{\mu}_{\mathrm{C}}(\boldsymbol{k}'_{\mathrm{C}},\mu'_j;\boldsymbol{k}_{\mathrm{C}},\mu_j;K_{\mathrm{e}}) &= \left[J^{\mu}_{\mathrm{C}}(\boldsymbol{k}'_{\mathrm{C}},\mu'_j;\boldsymbol{k}_{\mathrm{C}},\mu_j;K_{\mathrm{e}})\right]^{\dagger} \\ &= J^{\mu *}_{\mathrm{C}}(\boldsymbol{k}_{\mathrm{C}},\mu_j;\boldsymbol{k}'_{\mathrm{C}},\mu'_j;K_{\mathrm{e}})\,, \end{aligned} \tag{4.23}$$

which amounts to showing invariance under interchange of all primed with unprimed momenta and spins and complex conjugation. To this we show hermiticity of the bound-state current Eq. (4.21) as follows: we write down $J^{\mu *}_{\mathrm{C}}(\boldsymbol{k}_{\mathrm{C}},\mu_j;\boldsymbol{k}'_{\mathrm{C}},\mu'_j;K_{\mathrm{e}})$ from Eq. (4.21) by interchanging all primed and unprimed momenta and spins and perform complex conjugation:

$$\begin{aligned} & J^{\mu *}_{\mathrm{C}}(\boldsymbol{k}_{\mathrm{C}},\mu_j;\boldsymbol{k}'_{\mathrm{C}},\mu'_j;K_{\mathrm{e}}) \\ &= \sqrt{k^0_{\mathrm{C}}k'^0_{\mathrm{C}}}\sum\int\frac{\mathrm{d}^3\tilde{k}_1}{k'^0_1}\sqrt{\frac{m_{12'}}{m_{12}}}\sqrt{\frac{k'^0_{12}}{k^0_{12}}} \\ &\quad \times Y^*_{l'\mu'_l}(\hat{\tilde{\boldsymbol{k}}}')C^{s'\mu'_s *}_{\frac{1}{2}\tilde{\mu}'_1\frac{1}{2}\tilde{\mu}'_2}C^{j\mu'_j *}_{l'\mu'_l s'\mu'_s}u^{j*}_{nl's'}(\tilde{k}')Y_{l\mu_l}(\hat{\tilde{\boldsymbol{k}}})C^{s\mu_s}_{\frac{1}{2}\tilde{\mu}_1\frac{1}{2}\tilde{\mu}_2}C^{j\mu_j}_{l\mu_l s\mu_s}u^{j}_{nls}(\tilde{k}) \\ &\quad \times D^{\frac{1}{2}*}_{\tilde{\mu}_1\mu_1}\left[\underline{R}^{-1}_{\mathrm{W_c}}\left(\tilde{w}_1,B_{\mathrm{c}}(\boldsymbol{w}_{12})\right)\right]D^{\frac{1}{2}*}_{\mu'_1\tilde{\mu}'_1}\left[\underline{R}_{\mathrm{W_c}}\left(\tilde{w}'_1,B_{\mathrm{c}}(\boldsymbol{w}'_{12})\right)\right] \\ &\quad \times D^{\frac{1}{2}*}_{\tilde{\mu}_2\tilde{\mu}'_2}\left[\underline{R}_{\mathrm{W_c}}\left(\tilde{w}'_2,B^{-1}_{\mathrm{c}}(\boldsymbol{w}_{12})B_{\mathrm{c}}(\boldsymbol{w}'_{12})\right)\right] \\ &\quad \times|\,\mathrm{e}\,|\left[\bar{u}_{\mu_1}(\boldsymbol{k}_1)(\mathit{\Gamma}_1+\mathit{\Gamma}_2)^{\mu}u_{\mu'_1}(\boldsymbol{k}'_1)\right]^*\,. \end{aligned} \tag{4.24}$$

Next we transform the integration measure in Eq. (4.24) according to Eq. (E.4)

$$\mathrm{d}^3\tilde{k}_1=\mathrm{d}^3\tilde{k}'_1\frac{m_{12}}{m'_{12}}\frac{k^0_{12}}{k'^0_{12}}\frac{k'^0_1}{k^0_1} \tag{4.25}$$

since $\mathrm{d}^3k'_1=\mathrm{d}^3k_1$. Further the Wigner D-functions can be rewritten in their original form by using Eq. (C.5). Finally we use the hermiticity of the constituent current, Eq. (B.22), to rewrite it in its original form. This shows that the right-hand sides of Eq. (4.24) and Eq. (4.23) are equal.

4.4.2 Covariance

In this section we discuss the covariance properties of the current given by Eq. (4.21). For simplicity, we restrict our investigation to the case of a pure s-wave with $l=l'=0$, which has already been discussed in Sec. 3.4.2. In this case the spherical harmonics become a constant, $Y^*_{00}(\hat{\tilde{\boldsymbol{k}}}')=Y_{00}(\hat{\tilde{\boldsymbol{k}}})=1/\sqrt{4\pi}$ and the Clebsch-Gordans become Kronecker deltas, $C^{j\mu'_j *}_{00s'\mu'_s}=\delta_{s'j}\delta_{\mu'_s\mu'_j}$ and $C^{j\mu_j}_{00s\mu_s}=$

$\delta_{sj}\delta_{\mu_s\mu_j}$. Then the expression of the bound-state current, after summation and reordering, reads

$$\begin{aligned}
&J^\mu_{\mathrm{C}}(\boldsymbol{k}'_{\mathrm{C}},\mu'_j;\boldsymbol{k}_{\mathrm{C}},\mu_j;K_{\mathrm{e}})\\
&= \frac{1}{4\pi}\sqrt{k^0_{\mathrm{C}}k'^0_{\mathrm{C}}}\sum\int\frac{\mathrm{d}^3\tilde{k}'_1}{k^0_1}\sqrt{\frac{m_{12}}{m'_{12}}}\sqrt{\frac{k^0_{12}}{k'^0_{12}}}u^*_{n0}(\tilde{k}')u_{n0}(\tilde{k})\\
&\quad\times D^{\frac{1}{2}}_{\tilde{\mu}'_1\mu'_1}\left[\underline{R}^{-1}_{\mathrm{W_c}}\left(\tilde{w}'_1,B_{\mathrm{c}}(\boldsymbol{w}'_{12})\right)\right]C^{j'\mu'_j*}_{\frac{1}{2}\tilde{\mu}'_1\frac{1}{2}\tilde{\mu}'_2}\\
&\quad\times D^{\frac{1}{2}}_{\tilde{\mu}'_2\tilde{\mu}_2}\left[\underline{R}_{\mathrm{W_c}}\left(\tilde{w}_2,B^{-1}_{\mathrm{c}}(\boldsymbol{w}'_{12})B_{\mathrm{c}}(\boldsymbol{w}_{12})\right)\right]\\
&\quad\times C^{j\mu_j}_{\frac{1}{2}\tilde{\mu}_1\frac{1}{2}\tilde{\mu}_2}D^{\frac{1}{2}}_{\mu_1\tilde{\mu}_1}\left[\underline{R}_{\mathrm{W_c}}\left(\tilde{w}_1,B_{\mathrm{c}}(\boldsymbol{w}_{12})\right)\right]\\
&\quad\times|\,\mathrm{e}\,|\,\bar{u}_{\mu'_1}(\boldsymbol{k}'_1)(\mathit{\Gamma}_1+\mathit{\Gamma}_2)^\mu u_{\mu_1}(\boldsymbol{k}_1)\,. \qquad (4.26)
\end{aligned}$$

In App. D.2.2 we prove that this bound-state current associated with the center-of-mass system has the same transformation properties under Lorentz transformations as the center-of-mass currents of Eq. (3.82):

$$\begin{aligned}
&J^\mu_{\mathrm{C}}(\boldsymbol{k}'_{\mathrm{C}},\mu'_j;\boldsymbol{k}_{\mathrm{C}},\mu_j;K_{\mathrm{e}})\\
&\xrightarrow{\mathit{\Lambda}}\; J^\mu_{\mathrm{C}}(\boldsymbol{R}_{\mathrm{W_c}}(V,\mathit{\Lambda})k'_{\mathrm{C}},\bar{\mu}'_j;\boldsymbol{R}_{\mathrm{W_c}}(V,\mathit{\Lambda})k_{\mathrm{C}},\bar{\mu}_j;R_{\mathrm{W_c}}(V,\mathit{\Lambda})K_{\mathrm{e}})\\
&=\; R_{\mathrm{W_c}}(V,\mathit{\Lambda})^\mu{}_\nu J^\nu_{\mathrm{C}}(\boldsymbol{k}'_{\mathrm{C}},\mu'_j;\boldsymbol{k}_{\mathrm{C}},\mu_j;K_{\mathrm{e}})D^j_{\mu_j\bar{\mu}_j}(\underline{R}^{-1}_{\mathrm{W_c}}(V,\mathit{\Lambda}))D^{j*}_{\mu'_j\bar{\mu}'_j}(\underline{R}^{-1}_{\mathrm{W_c}}(V,\mathit{\Lambda}))\,. \qquad (4.27)
\end{aligned}$$

This serves as a reasonableness check of our microscopic bound-state current, cf. Eq. (4.17), expressed in terms of wave functions and constituent current. The bound-state current with the correct covariance properties is obtained in the same way as for the phenomenological currents, cf. Eq. (3.83), namely by going to the physical particle momenta and corresponding spins by means of a canonical boost [BSFK09]:

$$\begin{aligned}
&J^\mu_{\mathrm{C}}(\boldsymbol{p}'_{\mathrm{C}},\sigma'_j;\boldsymbol{p}_{\mathrm{C}},\sigma_j;P_{\mathrm{e}})\\
&:= B_{\mathrm{c}}(\boldsymbol{V})^\mu{}_\nu J^\nu_{\mathrm{C}}(\boldsymbol{k}'_{\mathrm{C}},\mu'_j;\boldsymbol{k}_{\mathrm{C}},\mu_j;K_{\mathrm{e}})\\
&\quad\times D^{j*}_{\mu'_j\sigma'_j}(\underline{R}^{-1}_{\mathrm{W_c}}(w'_{\mathrm{C}},B_{\mathrm{c}}(\boldsymbol{V})))D^j_{\mu_j\sigma_j}(\underline{R}^{-1}_{\mathrm{W_c}}(w_{\mathrm{C}},B_{\mathrm{c}}(\boldsymbol{V})))\\
&= \frac{1}{4\pi}\sqrt{k^0_{\mathrm{C}}k'^0_{\mathrm{C}}}\sum\int\frac{\mathrm{d}^3\tilde{k}'_1}{k^0_1}\sqrt{\frac{m_{12}}{m'_{12}}}\sqrt{\frac{k^0_{12}}{k'^0_{12}}}u^*_{n0}(\tilde{k}')u_{n0}(\tilde{k})\\
&\quad\times D^{\frac{1}{2}*}_{\sigma'_1\tilde{\mu}'_1}\left[\underline{R}_{\mathrm{W_c}}\left(\tilde{w}'_1,B_{\mathrm{c}}(\boldsymbol{V})B_{\mathrm{c}}(\boldsymbol{w}'_{12})\right)\right]C^{j'\mu'_j*}_{\frac{1}{2}\tilde{\mu}'_1\frac{1}{2}\tilde{\mu}'_2}\\
&\quad\times D^{\frac{1}{2}}_{\tilde{\mu}'_2\tilde{\mu}_2}\left[\underline{R}_{\mathrm{W_c}}\left(\tilde{w}_2,B^{-1}_{\mathrm{c}}(\boldsymbol{w}'_{12})B_{\mathrm{c}}(\boldsymbol{w}_{12})\right)\right]\\
&\quad\times C^{j\mu_j}_{\frac{1}{2}\tilde{\mu}_1\frac{1}{2}\tilde{\mu}_2}D^{\frac{1}{2}}_{\sigma_1\tilde{\mu}_1}\left[\underline{R}_{\mathrm{W_c}}\left(\tilde{w}_1,B_{\mathrm{c}}(\boldsymbol{V})B_{\mathrm{c}}(\boldsymbol{w}_{12})\right)\right]\\
&\quad\times|\,\mathrm{e}\,|\,\bar{u}_{\sigma'_1}(\boldsymbol{p}'_1)(\mathit{\Gamma}_1+\mathit{\Gamma}_2)^\mu u_{\sigma_1}(\boldsymbol{p}_1)\\
&\quad\times D^{j*}_{\mu'_j\sigma'_j}(\underline{R}^{-1}_{\mathrm{W_c}}(w'_{\mathrm{C}},B_{\mathrm{c}}(\boldsymbol{V})))D^j_{\mu_j\sigma_j}(\underline{R}^{-1}_{\mathrm{W_c}}(w_{\mathrm{C}},B_{\mathrm{c}}(\boldsymbol{V})))\,, \qquad (4.28)
\end{aligned}$$

with $w^{(\prime)}_{\mathrm{C}} := k^{(\prime)}_{\mathrm{C}}/m^{(\prime)}_{\mathrm{C}}$. Here we have used the transformation properties of the constituent current, Eq. (3.82). The covariant current $J^\mu_{\mathrm{C}}(\boldsymbol{p}'_{\mathrm{C}},\sigma'_j;\boldsymbol{p}_{\mathrm{C}},\sigma_j;P_{\mathrm{e}})$ of

Eq. (4.28) transforms like a four-vector under Lorentz transformations. The corresponding proof is carried out in a similar manner as for the constituent currents in App. D.2.1.

4.4.3 Pseudoscalar Current

In this section we consider our bound-state current of Eq. (4.19) for the case of the bound state being a charged, massive pseudoscalar particle (PS) with $j = 0$ such as a $\pi^\pm$ meson (charged pion). In the constituent quark model a pseudoscalar meson is described by a confined quark-antiquark ($\mathrm{q\bar{q}}$) pair. In particular, π^+ is a bound state of a u-quark and a $\bar{\mathrm{d}}$-quark.

Simplifications

In the case of $j = 0$ and a pure s-wave the Clebsch-Gordan coefficients in the wave functions of Eq. (4.19) can be written as

$$C^{00*}_{\frac{1}{2}\tilde{\mu}'_1\,\frac{1}{2}\tilde{\mu}'_2} = \frac{(-1)^{\frac{1}{2}-\tilde{\mu}'_1}}{\sqrt{2}}\delta_{\tilde{\mu}'_2-\tilde{\mu}'_1}\,, \quad C^{00}_{\frac{1}{2}\tilde{\mu}_1\,\frac{1}{2}\tilde{\mu}_2} = \frac{(-1)^{\frac{1}{2}-\tilde{\mu}_1}}{\sqrt{2}}\delta_{\tilde{\mu}_2-\tilde{\mu}_1}\,. \tag{4.29}$$

With these Kronecker deltas the sums over $\tilde{\mu}_2$ and $\tilde{\mu}'_2$ can be carried out. Then the product of the Clebsch-Gordan coefficients with the Wigner D-function for the inactive constituent 2 becomes

$$\begin{aligned}
&\frac{1}{2}(-1)^{1-\tilde{\mu}_1-\tilde{\mu}'_1} D^{\frac{1}{2}}_{-\tilde{\mu}'_1-\tilde{\mu}_1}\left[\underline{R}_{\mathrm{W_c}}\left(\tilde{w}_2, B_{\mathrm{c}}^{-1}(\boldsymbol{w}'_{12})B_{\mathrm{c}}(\boldsymbol{w}_{12})\right)\right] \\
&\quad = \frac{1}{2} D^{\frac{1}{2}}_{\tilde{\mu}_1\tilde{\mu}'_1}\left[\underline{R}^{-1}_{\mathrm{W_c}}\left(\tilde{w}_2, B_{\mathrm{c}}^{-1}(\boldsymbol{w}'_{12})B_{\mathrm{c}}(\boldsymbol{w}_{12})\right)\right]\,.
\end{aligned} \tag{4.30}$$

Here we have made use of the properties of the Wigner D-functions, Eqs. (C.5) and (C.8). Using this expression allows us to combine all three D-functions to a single one. With these findings the current for a pseudoscalar particle reads

$$\begin{aligned}
&J^{\mu}_{\mathrm{PS}}(\boldsymbol{k}'_{\mathrm{C}}, \boldsymbol{k}_{\mathrm{C}}, K_{\mathrm{e}}) \\
&\quad = \frac{1}{4\pi}\frac{\sqrt{k^0_{\mathrm{C}}k'^0_{\mathrm{C}}}}{2}\int \frac{\mathrm{d}^3\tilde{k}'_1}{k^0_1}\sqrt{\frac{m_{12}}{m'_{12}}}\sqrt{\frac{k^0_{12}}{k'^0_{12}}}\,u^*_{n0}(\tilde{k}')u_{n0}(\tilde{k}) \\
&\qquad \times \sum_{\mu'_1\mu_1} D^{\frac{1}{2}}_{\mu_1\mu'_1}\left[\underline{R}_{\mathrm{W_c}}\left(\tilde{w}_1, B_{\mathrm{c}}(\boldsymbol{w}_{12})\right)\right. \\
&\qquad\quad \left.\times\, \underline{R}^{-1}_{\mathrm{W_c}}\left(\tilde{w}_2, B_{\mathrm{c}}^{-1}(\boldsymbol{w}'_{12})B_{\mathrm{c}}(\boldsymbol{w}_{12})\right)\underline{R}^{-1}_{\mathrm{W_c}}\left(\tilde{w}'_1, B_{\mathrm{c}}(\boldsymbol{w}'_{12})\right)\right] \\
&\qquad \times |\,\mathrm{e}\,|\,\bar{u}_{\mu'_1}(\boldsymbol{k}'_1)(\mathit{\Gamma}_1+\mathit{\Gamma}_2)^{\mu}u_{\mu_1}(\boldsymbol{k}_1)\,.
\end{aligned} \tag{4.31}$$

The argument of the single Wigner D-function in this expression can be simplified by using some relations for canonical boosts in the SL(2,ℂ) representation, which are collected in App. C.1:

$$\begin{aligned}
&\underline{R}_{\mathrm{W_c}}\left(\tilde{w}_1, B_{\mathrm{c}}(\boldsymbol{w}_{12})\right)\underline{R}^{-1}_{\mathrm{W_c}}\left(\tilde{w}_2, B_{\mathrm{c}}^{-1}(\boldsymbol{w}'_{12})B_{\mathrm{c}}(\boldsymbol{w}_{12})\right)\underline{R}^{-1}_{\mathrm{W_c}}\left(\tilde{w}'_1, B_{\mathrm{c}}(\boldsymbol{w}'_{12})\right) \\
&\quad = \underline{B}_{\mathrm{c}}(\boldsymbol{w}_1)\,\sigma_\tau \begin{pmatrix} w^0_{12} \\ -\boldsymbol{w}_{12} \end{pmatrix}^{\tau} \underline{w}_2\,\sigma_\nu \begin{pmatrix} w'^0_{12} \\ -\boldsymbol{w}'_{12} \end{pmatrix}^{\nu} \underline{B}_{\mathrm{c}}(\boldsymbol{w}'_1)\,.
\end{aligned} \tag{4.32}$$

With this simplification and going back to physical momenta the covariant current for a pseudoscalar bound state finally reads

$$\begin{aligned}
&J^{\mu}_{\mathrm{PS}}(\boldsymbol{p}'_{\mathrm{C}}, \boldsymbol{p}_{\mathrm{C}}, P_{\mathrm{e}}) \\
&= \quad \frac{1}{4\pi} \frac{\sqrt{k^0_{\mathrm{C}} k'^0_{\mathrm{C}}}}{2} \int \frac{\mathrm{d}^3\tilde{k}'_1}{k^0_1} \sqrt{\frac{m_{12}}{m'_{12}}} \sqrt{\frac{k^0_{12}}{k'^0_{12}}} u^*_{n0}(\tilde{k}') u_{n0}(\tilde{k}) \\
&\quad \times \sum_{\sigma'_1 \sigma_1} D^{\frac{1}{2}}_{\sigma_1 \sigma'_1} \Bigg[\underline{B}_{\mathrm{c}}(\boldsymbol{v}_1) \sigma_\tau B_{\mathrm{c}}(-\boldsymbol{V})^{\tau}{}_{\rho} \begin{pmatrix} v^0_{12} \\ -\boldsymbol{v}_{12} \end{pmatrix}^{\rho} \underline{v}_2 \\
&\quad \times \sigma_\nu B_{\mathrm{c}}(-\boldsymbol{V})^{\nu}{}_{\lambda} \begin{pmatrix} v'^0_{12} \\ -\boldsymbol{v}'_{12} \end{pmatrix}^{\lambda} \underline{B}_{\mathrm{c}}(\boldsymbol{v}'_1) \Bigg] \\
&\quad \times |\,\mathrm{e}\,| \, \bar{u}_{\sigma'_1}(\boldsymbol{p}'_1) (\mathit{\Gamma}_1 + \mathit{\Gamma}_2)^{\mu} u_{\sigma_1}(\boldsymbol{p}_1) \, . \qquad (4.33)
\end{aligned}$$

Continuity

The microscopic current for a pseudoscalar bound system of Eq. (4.33) satisfies the condition of current conservation, cf. Eq. (3.66), which reads

$$(p'_{\mathrm{C}} - p_{\mathrm{C}})_\mu J^{\mu}_{\mathrm{PS}}(\boldsymbol{p}'_{\mathrm{C}}, \boldsymbol{p}_{\mathrm{C}}, P_{\mathrm{e}}) = (k'_{\mathrm{C}} - k_{\mathrm{C}})_\mu J^{\mu}_{\mathrm{PS}}(\boldsymbol{k}'_{\mathrm{C}}, \boldsymbol{k}_{\mathrm{C}}, K_{\mathrm{e}}) = 0 \, . \qquad (4.34)$$

The rather lengthy analytical proof of Eq. (4.34) is given in App. D.3.1. It amounts to showing that the integral in Eq. (4.33) vanishes if the spinor product $\bar{u}_{\mu'_1}(\boldsymbol{k}'_1)\gamma_\nu u_{\mu_1}(\boldsymbol{k}_1)$ is replaced by $\bar{u}_{\mu'_1}(\boldsymbol{k}'_1)\boldsymbol{\gamma} \cdot (\boldsymbol{k}_1 - \boldsymbol{k}'_1) u_{\mu_1}(\boldsymbol{k}_1)$. By a change of the integration variables $\mathrm{d}^3\tilde{k}'_1 \to \mathrm{d}^3\tilde{k}_1$ it can be shown that the integral over $\bar{u}_{\mu'_1}(\boldsymbol{k}'_1)\boldsymbol{\gamma} \cdot \boldsymbol{k}'_1 u_{\mu_1}(\boldsymbol{k}_1)$ goes over into the integral over $\bar{u}_{\mu'_1}(\boldsymbol{k}'_1)\boldsymbol{\gamma} \cdot \boldsymbol{k}_1 u_{\mu_1}(\boldsymbol{k}_1)$ (and vice versa) so that the difference of them vanishes.

4.4.4 Vector Current

In this work we also consider charged, massive vector bound states with $j = 1$. Examples for such systems are, e.g., the $\rho^{\pm}$ meson and the deuteron D. In the constituent quark model the ρ^{+} meson is, like the π^{+}, considered as a confined pair of a u-quark and a $\bar{\mathrm{d}}$-quark. The deuteron, the simplest of all nuclei, is composed of a proton p and a neutron n. In the following we do not further resolve the proton and the neutron in terms of quarks and gluons. Instead, the structure of the nucleons is taken into account in terms of phenomenological electromagnetic nucleon form factors, cf. Eq. (3.75).

Simplifications

For $j = 1$ and the case of a pure s-wave the Clebsch-Gordan coefficients in the wave functions of Eq. (4.19), $C^{1\mu_j}_{\frac{1}{2}\tilde{\mu}_1 \frac{1}{2}\tilde{\mu}_2}$ and $C^{1\mu'_j *}_{\frac{1}{2}\tilde{\mu}'_1 \frac{1}{2}\tilde{\mu}'_2}$, can be expressed in (2×2)-matrix form as [BG79]

$$C^{1\mu_j}_{\frac{1}{2}\tilde{\mu}_1 \frac{1}{2}\tilde{\mu}_2} = \epsilon^{\mu}_{\mu_j}(\mathbf{0}) \left(\sigma_\mu \frac{\varepsilon}{\sqrt{2}} \right)_{\tilde{\mu}_1 \tilde{\mu}_2} , \qquad (4.35)$$

$$C^{1\mu'_j *}_{\frac{1}{2}\tilde{\mu}'_1 \frac{1}{2}\tilde{\mu}'_2} = -\epsilon^{*\mu}_{\mu'_j}(\mathbf{0}) \left(\frac{\varepsilon}{\sqrt{2}} \sigma_\mu \right)_{\tilde{\mu}'_2 \tilde{\mu}'_1} . \qquad (4.36)$$

Here $\varepsilon = \mathrm{i}\,\sigma_2$ is the metric spinor and $\epsilon^{\mu}_{\mu_j^{(\prime)}}(\mathbf{0})$ are the polarization vectors for massive spin-1 particles in the rest frame given in App. B.3.1. Using Lorentz invariance, cf. Eq. (B.40) and inserting for the Clebsch-Gordan coefficients into Eq. (4.26) gives

$$\begin{aligned}
&J^{\mu}_{\mathrm{V}}(\boldsymbol{k}'_{\mathrm{C}}, \mu'_j; \boldsymbol{k}_{\mathrm{C}}, \mu_j; K_{\mathrm{e}}) \\
&\quad = \frac{1}{2}\epsilon^{*\sigma}_{\mu'_j}(\boldsymbol{k}'_{\mathrm{C}})\epsilon^{\tau}_{\mu_j}(\boldsymbol{k}_{\mathrm{C}})B_{\mathrm{c}}(-\boldsymbol{w}'_{\mathrm{C}})^{\lambda}{}_{\sigma}B_{\mathrm{c}}(-\boldsymbol{w}_{\mathrm{C}})^{\nu}{}_{\tau} \\
&\qquad \times\frac{1}{4\pi}\sqrt{k^0_{\mathrm{C}}k'^0_{\mathrm{C}}}\sum\int\frac{\mathrm{d}^3\tilde{k}'_1}{k^0_1}\sqrt{\frac{m_{12}}{m'_{12}}}\sqrt{\frac{k^0_{12}}{k'^0_{12}}}u^*_{n0}(\tilde{k}')u_{n0}(\tilde{k}) \\
&\qquad \times D^{\frac{1}{2}}_{\mu_1\tilde{\mu}_1}\left[\underline{R}_{\mathrm{W_c}}\left(\tilde{w}_1, B_{\mathrm{c}}(\boldsymbol{w}_{12})\right)\right](\sigma_{\nu})_{\tilde{\mu}_1\tilde{\mu}_2} \\
&\qquad \times D^{\frac{1}{2}}_{\tilde{\mu}_2\tilde{\mu}'_2}\left[\underline{R}_{\mathrm{W_c}}\left(\tilde{w}'_2, B^{-1}_{\mathrm{c}}(\boldsymbol{w}_{12})B_{\mathrm{c}}(\boldsymbol{w}'_{12})\right)\right] \\
&\qquad \times(\sigma_{\lambda})_{\tilde{\mu}'_2\tilde{\mu}'_1}D^{\frac{1}{2}}_{\tilde{\mu}'_1\mu'_1}\left[\underline{R}^{-1}_{\mathrm{W_c}}\left(\tilde{w}'_1, B_{\mathrm{c}}(\boldsymbol{w}'_{12})\right)\right] \\
&\qquad \times|\mathrm{e}|\,\bar{u}_{\mu'_1}(\boldsymbol{k}'_1)(\mathit{\Gamma}_1+\mathit{\Gamma}_2)^{\mu}u_{\mu_1}(\boldsymbol{k}_1)\,,
\end{aligned} \tag{4.37}$$

where we have used Eq. (C.9). The current with the correct covariance properties is then obtained from Eq. (4.37) according to Eq. (4.28):

$$\begin{aligned}
&J^{\mu}_{\mathrm{V}}(\boldsymbol{p}'_{\mathrm{C}}, \sigma'_j; \boldsymbol{p}_{\mathrm{C}}, \sigma_j; P_{\mathrm{e}}) \\
&\quad = \frac{1}{2}B_{\mathrm{c}}(-\boldsymbol{V})^{\sigma}{}_{\kappa}\epsilon^{*\kappa}_{\sigma'_j}(\boldsymbol{p}'_{\mathrm{C}})B_{\mathrm{c}}(-\boldsymbol{V})^{\tau}{}_{\omega}\epsilon^{\omega}_{\sigma_j}(\boldsymbol{p}_{\mathrm{C}})B_{\mathrm{c}}(-\boldsymbol{w}'_{\mathrm{C}})^{\lambda}{}_{\sigma}B_{\mathrm{c}}(-\boldsymbol{w}_{\mathrm{C}})^{\nu}{}_{\tau} \\
&\qquad \times\frac{1}{4\pi}\sqrt{k^0_{\mathrm{C}}k'^0_{\mathrm{C}}}\sum\int\frac{\mathrm{d}^3\tilde{k}'_1}{k^0_1}\sqrt{\frac{m_{12}}{m'_{12}}}\sqrt{\frac{k^0_{12}}{k'^0_{12}}}u^*_{n0}(\tilde{k}')u_{n0}(\tilde{k}) \\
&\qquad \times D^{\frac{1}{2}}_{\sigma_1\tilde{\mu}_1}\left[\underline{R}_{\mathrm{W_c}}\left(\tilde{w}_1, B_{\mathrm{c}}(\boldsymbol{V})B_{\mathrm{c}}(\boldsymbol{w}_{12})\right)\right](\sigma_{\nu})_{\tilde{\mu}_1\tilde{\mu}_2} \\
&\qquad \times D^{\frac{1}{2}}_{\tilde{\mu}_2\tilde{\mu}'_2}\left[\underline{R}_{\mathrm{W_c}}\left(\tilde{w}'_2, B^{-1}_{\mathrm{c}}(\boldsymbol{w}_{12})B_{\mathrm{c}}(\boldsymbol{w}'_{12})\right)\right] \\
&\qquad \times(\sigma_{\lambda})_{\tilde{\mu}'_2\tilde{\mu}'_1}D^{\frac{1}{2}}_{\tilde{\mu}'_1\sigma'_1}\left[\underline{R}_{\mathrm{W_c}}\left(v'_1, B^{-1}_{\mathrm{c}}(\boldsymbol{w}'_{12})B^{-1}_{\mathrm{c}}(\boldsymbol{V})\right)\right] \\
&\qquad \times|\mathrm{e}|\,\bar{u}_{\sigma'_1}(\boldsymbol{p}'_1)(\mathit{\Gamma}_1+\mathit{\Gamma}_2)^{\mu}u_{\sigma_1}(\boldsymbol{p}_1)\,,
\end{aligned} \tag{4.38}$$

where we have used Eq. (B.32). From Eq. (4.37) using

$$J^{\mu}_{\mathrm{V}}(\boldsymbol{k}'_{\mathrm{C}}, \mu'_j; \boldsymbol{k}_{\mathrm{C}}, \mu_j; K_{\mathrm{e}}) = J_{\mathrm{V}}(\boldsymbol{k}'_{\mathrm{C}}; \boldsymbol{k}_{\mathrm{C}}; K_{\mathrm{e}})^{\mu}_{\sigma\tau}\epsilon^{*\sigma}_{\mu'_j}(\boldsymbol{k}'_{\mathrm{C}})\epsilon^{\tau}_{\mu_j}(\boldsymbol{k}_{\mathrm{C}}) \tag{4.39}$$

we can read off the current tensor as

$$\begin{aligned}
&J_{\mathrm{V}}(\boldsymbol{k}'_{\mathrm{C}}, \boldsymbol{k}_{\mathrm{C}}, K_{\mathrm{e}})^{\mu}_{\sigma\tau} \\
&\quad := \frac{1}{2}B_{\mathrm{c}}(-\boldsymbol{w}'_{\mathrm{C}})^{\lambda}{}_{\sigma}B_{\mathrm{c}}(-\boldsymbol{w}_{\mathrm{C}})^{\nu}{}_{\tau} \\
&\qquad \times\frac{1}{4\pi}\sqrt{k^0_{\mathrm{C}}k'^0_{\mathrm{C}}}\sum\int\frac{\mathrm{d}^3\tilde{k}'_1}{k^0_1}\sqrt{\frac{m_{12}}{m'_{12}}}\sqrt{\frac{k^0_{12}}{k'^0_{12}}}u^*_{n0}(\tilde{k}')u_{n0}(\tilde{k}) \\
&\qquad \times D^{\frac{1}{2}}_{\mu_1\tilde{\mu}_1}\left[\underline{R}_{\mathrm{W_c}}\left(\tilde{w}_1, B_{\mathrm{c}}(\boldsymbol{w}_{12})\right)\right](\sigma_{\nu})_{\tilde{\mu}_1\tilde{\mu}_2} \\
&\qquad \times D^{\frac{1}{2}}_{\tilde{\mu}_2\tilde{\mu}'_2}\left[\underline{R}_{\mathrm{W_c}}\left(\tilde{w}'_2, B^{-1}_{\mathrm{c}}(\boldsymbol{w}_{12})B_{\mathrm{c}}(\boldsymbol{w}'_{12})\right)\right] \\
&\qquad \times(\sigma_{\lambda})_{\tilde{\mu}'_2\tilde{\mu}'_1}D^{\frac{1}{2}}_{\tilde{\mu}'_1\mu'_1}\left[\underline{R}^{-1}_{\mathrm{W_c}}\left(\tilde{w}'_1, B_{\mathrm{c}}(\boldsymbol{w}'_{12})\right)\right] \\
&\qquad \times|\mathrm{e}|\,\bar{u}_{\mu'_1}(\boldsymbol{k}'_1)(\mathit{\Gamma}_1+\mathit{\Gamma}_2)^{\mu}u_{\mu_1}(\boldsymbol{k}_1)\,.
\end{aligned} \tag{4.40}$$

This current tensor is independent of the incoming and outgoing spin projections μ_j and μ'_j. The covariant current tensor is then obtained analogously from Eq. (4.38) as

$$\begin{aligned}
& J_{\mathrm{V}}(\boldsymbol{p}'_{\mathrm{C}}, \boldsymbol{p}_{\mathrm{C}}, P_{\mathrm{e}})^{\mu}_{\kappa\omega} \\
:= {} & \frac{1}{2} B_{\mathrm{c}}(-\boldsymbol{V})^{\sigma}{}_{\kappa} B_{\mathrm{c}}(-\boldsymbol{V})^{\tau}{}_{\omega} B_{\mathrm{c}}(-\boldsymbol{w}'_{\mathrm{C}})^{\lambda}{}_{\sigma} B_{\mathrm{c}}(-\boldsymbol{w}_{\mathrm{C}})^{\nu}{}_{\tau} \\
& \times \frac{1}{4\pi} \sqrt{k^0_{\mathrm{C}} k'^0_{\mathrm{C}}} \sum \int \frac{\mathrm{d}^3 \tilde{k}'_1}{k^0_1} \sqrt{\frac{m_{12}}{m'_{12}}} \sqrt{\frac{k^0_{12}}{k'^0_{12}}} u^*_{n0}(\tilde{k}') u_{n0}(\tilde{k}) \\
& \times D^{\frac{1}{2}}_{\sigma_1 \tilde{\mu}_1} \left[\underline{R}_{\mathrm{W_c}} \left(\tilde{w}_1, B_{\mathrm{c}}(\boldsymbol{V}) B_{\mathrm{c}}(\boldsymbol{w}_{12}) \right) \right] (\sigma_{\nu})_{\tilde{\mu}_1 \tilde{\mu}_2} \\
& \times D^{\frac{1}{2}}_{\tilde{\mu}_2 \tilde{\mu}'_2} \left[\underline{R}_{\mathrm{W_c}} \left(\tilde{w}'_2, B^{-1}_{\mathrm{c}}(\boldsymbol{w}_{12}) B_{\mathrm{c}}(\boldsymbol{w}'_{12}) \right) \right] \\
& \times (\sigma_{\lambda})_{\tilde{\mu}'_2 \tilde{\mu}'_1} D^{\frac{1}{2}}_{\tilde{\mu}'_1 \sigma'_1} \left[\underline{R}_{\mathrm{W_c}} \left(v'_1, B^{-1}_{\mathrm{c}}(\boldsymbol{w}'_{12}) B^{-1}_{\mathrm{c}}(\boldsymbol{V}) \right) \right] \\
& \times |\,\mathrm{e}\,| \, \bar{u}_{\sigma'_1}(\boldsymbol{p}'_1) (\mathit{\Gamma}_1 + \mathit{\Gamma}_2)^{\mu} u_{\sigma_1}(\boldsymbol{p}_1) \, .
\end{aligned} \tag{4.41}$$

Continuity

Current conservation, Eq. (3.66) does, in general, not hold for the electromagnetic current we obtain for a vector bound system as given by Eq. (4.38). This means

$$\begin{aligned}
& (p'_{\mathrm{C}} - p_{\mathrm{C}})_{\mu} J^{\mu}_{\mathrm{V}}(\boldsymbol{p}'_{\mathrm{C}}, \sigma'_j; \boldsymbol{p}_{\mathrm{C}}, \sigma_j; P_{\mathrm{e}}) \\
= {} & -(\boldsymbol{k}'_{\mathrm{C}} - \boldsymbol{k}_{\mathrm{C}}) \cdot \boldsymbol{J}_{\mathrm{V}}(\boldsymbol{k}'_{\mathrm{C}}, \mu'_j; \boldsymbol{k}_{\mathrm{C}}, \mu_j; K_{\mathrm{e}}) \\
& \times D^{j*}_{\mu'_j \sigma'_j} [\underline{R}^{-1}_{\mathrm{W_c}}(w'_{\mathrm{C}}, B_{\mathrm{c}}(\boldsymbol{V}))] D^{j}_{\mu_j \sigma_j} [\underline{R}^{-1}_{\mathrm{W_c}}(w_{\mathrm{C}}, B_{\mathrm{c}}(\boldsymbol{V}))] \\
\neq {} & 0 \, .
\end{aligned} \tag{4.42}$$

This issue is discussed in more detail in App. D.3.2. There we explain that the reason for the failure of proving continuity is the fact that the product of the three Wigner D-functions together with the two Clebsch-Gordan coefficients in Eq. (4.28) *cannot* be written as one single Wigner D-function like in the pseudoscalar case. Consequently, the properties of the Wigner D-functions necessary for showing current conservation cannot be used. An analysis of the covariant structure of the current (4.38) together with numerical results support the non-vanishing of the left-hand side of Eq. (4.42).

Chapter 5

Electromagnetic Form Factors

5.1 Introduction

The invariant electron-bound-state scattering amplitude in the one-photon-exchange approximation is usually expressed as the contraction of the electron current with a bound-state current times the covariant photon propagator. The bound-state current is a sum of independent Lorentz covariants which are multiplied by Lorentz invariant functions, the so-called *electromagnetic form factors* of the bound-state. They are real functions of the four-momentum-transfer squared ($q^\mu q_\mu = -Q^2$) and they represent the observables that describe the electromagnetic structure of the (extended) bound-state. The aim of this chapter is to extract such electromagnetic form factors from the bound-state currents derived in the previous chapter and finally express them in terms of the bound-state wave functions.

5.2 Covariant Structure

In this section we investigate the covariant structure and the number of form factors needed to parametrize the bound-state currents derived previously. We start with the simple pseudoscalar case and then turn to the more complicated example of a spin-1 bound system.

5.2.1 Pseudoscalar Current

From covariance, continuity and macrocausality arguments it is clear that a correct physical current $I^\mu_{\mathrm{PS}}(\boldsymbol{p}'_{\mathrm{C}}, \boldsymbol{p}_{\mathrm{C}})$ of a pseudoscalar bound system should depend on only one covariant which is the sum of incoming and outgoing bound-state momenta $P_{\mathrm{C}} := p_{\mathrm{C}} + p'_{\mathrm{C}}$ times an electromagnetic form factor F of the bound system, with F being a function of Mandelstam $\mathrm{t} = -Q^2$. It turns out, however, that this is not the case for our electromagnetic current of a pseudoscalar bound system $J^\mu_{\mathrm{PS}}(\boldsymbol{p}'_{\mathrm{C}}, \boldsymbol{p}_{\mathrm{C}}, P_{\mathrm{e}})$, which we have derived from the one-photon-exchange optical potential. It does not have all the properties it should have. It satisfies current conservation and transforms like a four-vector, but it cannot be written as a sum of covariants times Lorentz invariants (Q^2 and m_{C}^2) which are solely built from the incoming and outgoing bound-state four-momenta (p_{C}^{μ} and $p_{\mathrm{C}}^{\mu\,\prime}$). Our current exhibits an additional dependence on P_{e} which has already been indicated. The general covariant structure of our current $J_{\mathrm{PS}}^{\mu}(\boldsymbol{p}_{\mathrm{C}}', \boldsymbol{p}_{\mathrm{C}}, P_{\mathrm{e}})$ can be derived from the following considerations: without spin one has, in general, four independent current components corresponding to the Lorentz indices $\mu = 0, \ldots, 3$. Hence, one needs four independent covariant structures multiplied by four form factors to parametrize the current. Due to the condition of current conservation, which is proved analytically in App. D.3.1, one component of the current can be expressed in terms of the other three, which eliminates one covariant structure. Another structure can be eliminated by the fact that the current $J_{\mathrm{PS}}^{\mu}(\boldsymbol{p}_{\mathrm{C}}', \boldsymbol{p}_{\mathrm{C}}, P_{\mathrm{e}})$ transforms covariantly under the Lorentz group. This means that the current can always be transformed into a frame where one of its components vanishes. Finally, we are left with just 2 independent components of the current. Therefore, the current can be expanded in terms of 2 conserved covariants times 2 form factors f and $\tilde{b}$. The expansion in terms of Lorentz covariants times form factors has to satisfy hermiticity. This has already been proved for the current in Sec. 4.4.1. Thus, the first of 2 covariants available is simply the sum of the incoming and outgoing bound-state momenta P_{C}. For the second covariant we have to recall that our derivation of the current is based on the Bakamjian-Thomas construction which is known to provide wrong cluster properties. This issue has already been discussed in Sec. 3.4.4. As a consequence, the physical properties of the bound state are not independent of an additional particle, in our case the electron. Therefore, we cannot be sure that the bound-state current we get does not also depend on the electron momenta. We actually find that our current cannot be fully expressed in terms of Hermitean bound-state covariants. The second current conserving Hermitean covariant available is the sum of the incoming and outgoing electron momenta P_{e}. This is the reason why we have included P_{e} as a further dependence in the argument of the bound-state current, cf. Eq. (3.79).

The only independent Lorentz invariants that can be built from the incoming and outgoing bound-state and electron momenta are Mandelstam t and Mandelstam s, i.e. the four-momentum-transfer squared and the square of the invariant mass of the electron-bound-state system, respectively. Therefore, wrong cluster properties may also influence the invariant vertex form factors f and $\tilde{b}$ such that they do not only depend on $\mathrm{t} = -Q^2$ but also on

$$\mathrm{s} = (p_{\mathrm{C}} + p_{\mathrm{e}})^2 = \left(\sqrt{m_{\mathrm{C}}^2 + \boldsymbol{k}_{\mathrm{C}}^2} + \sqrt{m_{\mathrm{e}}^2 + \boldsymbol{k}_{\mathrm{C}}^2}\right)^2 . \tag{5.1}$$

The s-dependence can equivalently be expressed as a dependence on the magnitude of the particle momenta

$$k := |\boldsymbol{k}_{\mathrm{C}}'| = |\boldsymbol{k}_{\mathrm{e}}'| = |\boldsymbol{k}_{\mathrm{C}}| = |\boldsymbol{k}_{\mathrm{e}}| , \tag{5.2}$$

which turns out to be more convenient for our purposes. Here we have used Eqs. (4.11) and (2.68). At this point it should be mentioned that Poincaré invariance of our Bakamjian-Thomas type approach would not be spoiled by vertex form factors that depend even on the whole set of independent Lorentz invariants involved in the process. A reasonable microscopic model for electromagnetic form factors should, of course, only depend on the momentum transfer squared t and not on s. Nevertheless, due to the non-locality of the vertex defined in Eq. (3.71) both form factors f and $\tilde{b}$ exhibit also a s-dependence. As we will see in the following, this dependence can, however, be eliminated in a certain limit.

With these findings we can write down our pseudoscalar bound-state current as a sum of Lorentz covariants times form factors [BKS11a, BKS11b]:[1]

$$\begin{aligned} J^\mu_{\mathrm{PS}}(\boldsymbol{p}'_{\mathrm{C}},\boldsymbol{p}_{\mathrm{C}},P_{\mathrm{e}}) &= |\,\mathrm{e}\,|\,[f(Q^2,k)P^\mu_{\mathrm{C}} + \tilde{b}(Q^2,k)P^\mu_{\mathrm{e}}] \\ &= |\,\mathrm{e}\,|\left[f(Q^2,k)P^\mu_{\mathrm{C}} + b(Q^2,k)P^\mu_{\mathrm{e}}\frac{P^2_{\mathrm{C}}}{P_{\mathrm{C}}\cdot P_{\mathrm{e}}}\right]. \end{aligned} \tag{5.3}$$

Here the factor $P^2_{\mathrm{C}}/P_{\mathrm{C}}\cdot P_{\mathrm{e}}$ has been separated from $\tilde{b}$ for convenience. The decomposition (5.3) holds for arbitrary values of the bound-state momenta p_{C} and p'_{C} with one exception: in the so-called *Breit frame*, i.e. backward scattering ($\boldsymbol{k}_{\mathrm{C}} = -\boldsymbol{k}'_{\mathrm{C}}$) in the electron-bound-state center-of-mass system. In this frame the two covariants P^μ_{C} and P^μ_{e} become proportional which precludes the separation of the two form factors.

It is clear that the two covariants P_{C} and P_{e} are not orthogonal to each other, i.e. $P_{\mathrm{C}}\cdot P_{\mathrm{e}} \neq 0$. If we choose, e.g., the second covariant as

$$P^\mu_\perp := P^\mu_{\mathrm{e}}\frac{P^2_{\mathrm{C}}}{P_{\mathrm{C}}\cdot P_{\mathrm{e}}} - P^\mu_{\mathrm{C}}\,, \tag{5.4}$$

which is orthogonal to P_{C}, then we have, in general, different form factors $\bar{f}$ and $\bar{b}$:

$$J^\mu_{\mathrm{PS}}(\boldsymbol{p}'_{\mathrm{C}},\boldsymbol{p}_{\mathrm{C}},P_{\mathrm{e}}) = |\,\mathrm{e}\,|\,[\bar{f}(Q^2,k)P^\mu_{\mathrm{C}} + \bar{b}(Q^2,k)P^\mu_\perp]\,. \tag{5.5}$$

Thus, there seems to be an ambiguity how to define the form factors by expanding the current in terms of covariants. It turns out, however, that only the form factor $f(Q^2,k)$ defined via the expansion (5.3) provides the correct charge of the bound state at $Q^2 = 0$, as it is required for the physical form factor. This justifies to call $f(Q^2,k)$ defined in Eq. (5.3) the *physical form factor* of the pseudoscalar bound state. The remaining structure in Eq. (5.3) that is proportional to P_{e} will then be referred to as *non-physical* (or *spurious*) contribution with $b(Q^2,k)$ being the *spurious form factor*. Hence, only the expansion (5.3) provides a sensible separation of the physical from the spurious contribution. The separation of Eq. (5.3) leads to the following definition: spurious contributions are defined as structures that depend on P_{e} [CDKM98].

By applying a canonical boost $B_{\mathrm{c}}(-\boldsymbol{V})$ to $J^\mu_{\mathrm{PS}}(\boldsymbol{p}'_{\mathrm{C}},\boldsymbol{p}_{\mathrm{C}},P_{\mathrm{e}})$ we find, according to Eq. (4.28) for the pseudoscalar case, the covariant structure of $J^\mu_{\mathrm{PS}}(\boldsymbol{k}'_{\mathrm{C}},\boldsymbol{k}_{\mathrm{C}},K_{\mathrm{e}})$:

$$\begin{aligned} J^\mu_{\mathrm{PS}}(\boldsymbol{k}'_{\mathrm{C}},\boldsymbol{k}_{\mathrm{C}},K_{\mathrm{e}}) &= B_{\mathrm{c}}(-\boldsymbol{V})^\mu{}_\nu J^\nu_{\mathrm{PS}}(\boldsymbol{p}'_{\mathrm{C}},\boldsymbol{p}_{\mathrm{C}},P_{\mathrm{e}}) \\ &= |\,\mathrm{e}\,|\left[f(Q^2,k)K^\mu_{\mathrm{C}} + b(Q^2,k)K^\mu_{\mathrm{e}}\frac{K^2_{\mathrm{C}}}{K_{\mathrm{C}}\cdot K_{\mathrm{e}}}\right] \\ &= |\,\mathrm{e}\,|\,[f(Q^2,k)K^\mu_{\mathrm{C}} + \tilde{b}(Q^2,k)K^\mu_{\mathrm{e}}]\,. \end{aligned} \tag{5.6}$$

---

[1] The covariant structure of our current resembles the corresponding one obtained in a covariant light-front approach of Refs. [KS94, CDKM98]. The relation between them will be discussed later.

5.2.2 Vector Current

A correct physical current $I^\mu_{\mathrm{V}}(\boldsymbol{p}'_{\mathrm{C}},\sigma'_j;\boldsymbol{p}_{\mathrm{C}},\sigma_j)$ of a vector bound system should depend on 3 form factors, F_1, F_2 and G_{M} which are functions of Mandelstam $\mathrm{t} = -Q^2$. Its covariant structure is usually obtained by constructing from the tensor $\epsilon^{\mu *}_{\sigma'_j}(\boldsymbol{p}'_{\mathrm{C}})\epsilon^{\nu}_{\sigma_j}(\boldsymbol{p}_{\mathrm{C}})$ all Hermitean, conserved four-vectors by appropriate multiplication and contraction with $\mathrm{g}^{\mu\nu}$, the sum P^μ_{C} and/or the difference $d^\mu := p'^\mu_{\mathrm{C}} - p^\mu_{\mathrm{C}}$ of the incoming and outgoing bound-state four-momenta.

However, as in the pseudoscalar case, the covariant structure of our bound-state current $J^\mu_{\mathrm{V}}(\boldsymbol{p}'_{\mathrm{C}},\sigma'_j;\boldsymbol{p}_{\mathrm{C}},\sigma_j;P_{\mathrm{e}})$ of Eq. (4.38), cannot be solely built from the incoming and outgoing momenta and spins of the bound state. Due to the violation of cluster separability in the Bakamjian-Thomas framework, we expect that it exhibits an additional dependence on the sum of the electron momenta P_{e}. Furthermore, unlike in the pseudoscalar case due to Eq. (4.42), we cannot demand current conservation and therefore we have to allow for non-conserved Lorentz structures proportional to d^μ.

The explicit construction of the covariant structure of $J^\mu_{\mathrm{V}}(\boldsymbol{p}'_{\mathrm{C}},\sigma'_j;\boldsymbol{p}_{\mathrm{C}},\sigma_j;P_{\mathrm{e}})$ is demonstrated in App. D.4. The analysis reveals that one can find 11 Hermitean covariants by contracting and/or multiplying the tensor $\epsilon^{\mu *}_{\sigma'_j}(\boldsymbol{p}'_{\mathrm{C}})\epsilon^{\nu}_{\sigma_j}(\boldsymbol{p}_{\mathrm{C}})$ with $\mathrm{g}^{\mu\nu}$ and/or the available four-vectors P^μ_{C}, d^μ and/or P^μ_{e}. Consequently, we can parametrize the current $J^\mu_{\mathrm{V}}(\boldsymbol{p}'_{\mathrm{C}},\sigma'_j;\boldsymbol{p}_{\mathrm{C}},\sigma_j;P_{\mathrm{e}})$ in terms of 11 form factors, the 3 physical form factors f_1, f_2 and g_{M} and 8 spurious form factors denoted $b_1,\ldots,b_8$. The form factors exhibit, due to the non-locality of the vertex in the Bakamjian-Thomas framework, an additional dependence on Mandelstam s. The expansion of the current in terms of the Hermitean covariants that are collected in (D.40), (D.41) and (D.42) times the form factors reads[2]

$$
\begin{aligned}
&\frac{1}{|\,\mathrm{e}\,|}\, J^\mu_{\mathrm{V}}(\boldsymbol{p}'_{\mathrm{C}},\sigma'_j;\boldsymbol{p}_{\mathrm{C}},\sigma_j;P_{\mathrm{e}}) \\
&= \left\{ f_1(Q^2,k)\epsilon^{*}_{\sigma'_j}(\boldsymbol{p}'_{\mathrm{C}})\cdot\epsilon_{\sigma_j}(\boldsymbol{p}_{\mathrm{C}}) + f_2(Q^2,k)\frac{[\epsilon^{*}_{\sigma'_j}(\boldsymbol{p}'_{\mathrm{C}})\cdot d][\epsilon_{\sigma_j}(\boldsymbol{p}_{\mathrm{C}})\cdot d]}{2m^2_{\mathrm{C}}} \right\} P^\mu_{\mathrm{C}} \\
&\quad + g_{\mathrm{M}}(Q^2,k)\left\{ \epsilon^{\mu *}_{\sigma'_j}(\boldsymbol{p}'_{\mathrm{C}})[\epsilon_{\sigma_j}(\boldsymbol{p}_{\mathrm{C}})\cdot d] - \epsilon^{\mu}_{\sigma_j}(\boldsymbol{p}_{\mathrm{C}})[\epsilon^{*}_{\sigma'_j}(\boldsymbol{p}'_{\mathrm{C}})\cdot d] \right\} \\
&\quad + \frac{m^2_{\mathrm{C}}}{P_{\mathrm{e}}\cdot P_{\mathrm{C}}} \left\{ b_1(Q^2,k)\epsilon^{*}_{\sigma'_j}(\boldsymbol{p}'_{\mathrm{C}})\cdot\epsilon_{\sigma_j}(\boldsymbol{p}_{\mathrm{C}}) + b_2(Q^2,k)\frac{[\epsilon^{*}_{\sigma'_j}(\boldsymbol{p}'_{\mathrm{C}})\cdot d][\epsilon_{\sigma_j}(\boldsymbol{p}_{\mathrm{C}})\cdot d]}{m^2_{\mathrm{C}}} \right. \\
&\quad + b_3(Q^2,k)\, 4m^2_{\mathrm{C}}\frac{[\epsilon^{*}_{\sigma'_j}(\boldsymbol{p}'_{\mathrm{C}})\cdot P_{\mathrm{e}}][\epsilon_{\sigma_j}(\boldsymbol{p}_{\mathrm{C}})\cdot P_{\mathrm{e}}]}{(P_{\mathrm{e}}\cdot P_{\mathrm{C}})^2} \\
&\quad \left. + b_4(Q^2,k)\frac{[\epsilon^{*}_{\sigma'_j}(\boldsymbol{p}'_{\mathrm{C}})\cdot d][\epsilon_{\sigma_j}(\boldsymbol{p}_{\mathrm{C}})\cdot P_{\mathrm{e}}] - [\epsilon^{*}_{\sigma'_j}(\boldsymbol{p}'_{\mathrm{C}})\cdot P_{\mathrm{e}}][\epsilon_{\sigma_j}(\boldsymbol{p}_{\mathrm{C}})\cdot d]}{P_{\mathrm{e}}\cdot P_{\mathrm{C}}} \right\} P^\mu_{\mathrm{e}} +
\end{aligned}
$$

---

[2] Like in the pseudoscalar case the covariant structure we obtain for our current resembles the corresponding ones of Refs. [KS94,CDKM98]. Thus, for later comparison, we have adopted the notation and normalizations of the spurious form factors of these works.

$$
\begin{aligned}
&+b_5(Q^2,k)\,4m_{\mathrm{C}}^2\frac{[\epsilon^*_{\sigma'_j}(\boldsymbol{p}'_{\mathrm{C}})\cdot P_{\mathrm{e}}][\epsilon_{\sigma_j}(\boldsymbol{p}_{\mathrm{C}})\cdot P_{\mathrm{e}}]}{(P_{\mathrm{e}}\cdot P_{\mathrm{C}})^2}P_{\mathrm{C}}^\mu \\
&+b_6(Q^2,k)\frac{[\epsilon^*_{\sigma'_j}(\boldsymbol{p}'_{\mathrm{C}})\cdot d][\epsilon_{\sigma_j}(\boldsymbol{p}_{\mathrm{C}})\cdot P_{\mathrm{e}}]-[\epsilon^*_{\sigma'_j}(\boldsymbol{p}'_{\mathrm{C}})\cdot P_{\mathrm{e}}][\epsilon_{\sigma_j}(\boldsymbol{p}_{\mathrm{C}})\cdot d]}{P_{\mathrm{e}}\cdot P_{\mathrm{C}}}P_{\mathrm{C}}^\mu \\
&+b_7(Q^2,k)\,2m_{\mathrm{C}}^2\frac{\epsilon^{\mu *}_{\sigma'_j}(\boldsymbol{p}'_{\mathrm{C}})[\epsilon_{\sigma_j}(\boldsymbol{p}_{\mathrm{C}})\cdot P_{\mathrm{e}}]+\epsilon^\mu_{\sigma_j}(\boldsymbol{p}_{\mathrm{C}})[\epsilon^*_{\sigma'_j}(\boldsymbol{p}'_{\mathrm{C}})\cdot P_{\mathrm{e}}]}{P_{\mathrm{e}}\cdot P_{\mathrm{C}}} \\
&+b_8(Q^2,k)\frac{[\epsilon^*_{\sigma'_j}(\boldsymbol{p}'_{\mathrm{C}})\cdot d][\epsilon_{\sigma_j}(\boldsymbol{p}_{\mathrm{C}})\cdot P_{\mathrm{e}}]+[\epsilon^*_{\sigma'_j}(\boldsymbol{p}'_{\mathrm{C}})\cdot P_{\mathrm{e}}][\epsilon_{\sigma_j}(\boldsymbol{p}_{\mathrm{C}})\cdot d]}{P_{\mathrm{e}}\cdot P_{\mathrm{C}}}\,d^\mu\,.
\end{aligned}
\tag{5.7}
$$

As in the pseudoscalar case there seems to be an ambiguity how to separate the physical from unphysical contributions. Again it turns out, however, that only the above decomposition with the associated definition of form factors gives the correct charge of the bound state at zero momentum transfer, as it is required for the physical charge form factor G_{C}. Again this justifies to define unphysical (or spurious) contributions as structures proportional to first or higher degrees of P_{e}, i.e. all structures multiplied by the spurious form factors $b_1, \ldots, b_8$ in Eq. (5.7).

By separation of the polarization vectors we find the covariant structure of the current tensor $J_{\mathrm{V}}(\boldsymbol{p}'_{\mathrm{C}},\boldsymbol{p}_{\mathrm{C}},P_{\mathrm{e}})^\mu_{\sigma\tau}$:

$$
\begin{aligned}
&\frac{1}{|\,\mathrm{e}\,|}\,J_{\mathrm{V}}(\boldsymbol{p}'_{\mathrm{C}},\boldsymbol{p}_{\mathrm{C}},P_{\mathrm{e}})^\mu_{\sigma\tau} \\
&\quad = \left\{f_1(Q^2,k)\mathrm{g}_{\sigma\tau}+f_2(Q^2,k)\frac{d_\sigma d_\tau}{2m_{\mathrm{C}}^2}\right\}P_{\mathrm{C}}^\mu+g_{\mathrm{M}}(Q^2,k)\left\{\mathrm{g}^\mu_\sigma d_\tau-\mathrm{g}^\mu_\tau d_\sigma\right\} \\
&\qquad +\left\{b_1(Q^2,k)\mathrm{g}_{\sigma\tau}+b_2(Q^2,k)\frac{d_\sigma d_\tau}{m_{\mathrm{C}}^2}+b_3(Q^2,k)4m_{\mathrm{C}}^2\frac{P_{\mathrm{e}\sigma}P_{\mathrm{e}\tau}}{(P_{\mathrm{e}}\cdot P_{\mathrm{C}})^2}\right. \\
&\qquad\quad \left.+b_4(Q^2,k)\frac{P_{\mathrm{e}\tau}d_\sigma-P_{\mathrm{e}\sigma}d_\tau}{P_{\mathrm{e}}\cdot P_{\mathrm{C}}}\right\}\frac{m_{\mathrm{C}}^2}{P_{\mathrm{e}}\cdot P_{\mathrm{C}}}P_{\mathrm{e}}^\mu \\
&\qquad +b_5(Q^2,k)\frac{P_{\mathrm{e}\sigma}P_{\mathrm{e}\tau}}{(P_{\mathrm{e}}\cdot P_{\mathrm{C}})^2}\,4m_{\mathrm{C}}^2P_{\mathrm{C}}^\mu+b_6(Q^2,k)\frac{P_{\mathrm{e}\tau}d_\sigma-P_{\mathrm{e}\sigma}d_\tau}{P_{\mathrm{e}}\cdot P_{\mathrm{C}}}P_{\mathrm{C}}^\mu \\
&\qquad +b_7(Q^2,k)\,2m_{\mathrm{C}}^2\frac{\mathrm{g}^\mu_\sigma P_{\mathrm{e}\tau}+\mathrm{g}^\mu_\tau P_{\mathrm{e}\sigma}}{P_{\mathrm{e}}\cdot P_{\mathrm{C}}}+b_8(Q^2,k)\frac{d_\sigma P_{\mathrm{e}\tau}+d_\tau P_{\mathrm{e}\sigma}}{P_{\mathrm{e}}\cdot P_{\mathrm{C}}}\,d^\mu\,.
\end{aligned}
\tag{5.8}
$$

The covariant structure of the bound-state current $J^\mu_{\mathrm{V}}(\boldsymbol{k}'_{\mathrm{C}},\mu'_j;\boldsymbol{k}_{\mathrm{C}},\mu_j;K_{\mathrm{e}})$ is then obtained by inverting Eq. (4.28), which means canonically boosting $J^\mu_{\mathrm{V}}(\boldsymbol{p}'_{\mathrm{C}},\sigma'_j;\boldsymbol{p}_{\mathrm{C}},\sigma_j;P_{\mathrm{e}})$ with $B_{\mathrm{c}}(-\boldsymbol{V})$ and multiplying with

$D^{1*}_{\sigma'_j\mu'_j}[\underline{R}_{\mathrm{W_c}}(w'_{\mathrm{C}}, B_{\mathrm{c}}(\boldsymbol{V}))]D^{1}_{\sigma_j\mu_j}[\underline{R}_{\mathrm{W_c}}(w_{\mathrm{C}}, B_{\mathrm{c}}(\boldsymbol{V}))]$:

$$
\begin{aligned}
&\frac{1}{|\,\mathrm{e}\,|}\,J^{\mu}_{\mathrm{V}}(\boldsymbol{k}'_{\mathrm{C}},\mu'_j;\boldsymbol{k}_{\mathrm{C}},\mu_j;K_{\mathrm{e}}) \\
&\quad= \frac{1}{|\,\mathrm{e}\,|}\,B_{\mathrm{c}}(-\boldsymbol{V})^{\mu}{}_{\nu}J^{\nu}_{\mathrm{V}}(\boldsymbol{p}'_{\mathrm{C}},\sigma'_j;\boldsymbol{p}_{\mathrm{C}},\sigma_j;P_{\mathrm{e}}) \\
&\qquad\times D^{1*}_{\sigma'_j\mu'_j}[\underline{R}_{\mathrm{W_c}}(w'_{\mathrm{C}}, B_{\mathrm{c}}(\boldsymbol{V}))]D^{1}_{\sigma_j\mu_j}[\underline{R}_{\mathrm{W_c}}(w_{\mathrm{C}}, B_{\mathrm{c}}(\boldsymbol{V}))] \\
&\quad= \left\{ f_1(Q^2,k)\epsilon^{*}_{\mu'_j}(\boldsymbol{k}'_{\mathrm{C}})\cdot\epsilon_{\mu_j}(\boldsymbol{k}_{\mathrm{C}}) + f_2(Q^2,k)\frac{[\epsilon^{*}_{\mu'_j}(\boldsymbol{k}'_{\mathrm{C}})\cdot q][\epsilon_{\mu_j}(\boldsymbol{k}_{\mathrm{C}})\cdot q]}{2m^2_{\mathrm{C}}} \right\} K^{\mu}_{\mathrm{C}} \\
&\qquad+g_{\mathrm{M}}(Q^2,k)\left\{\epsilon^{\mu *}_{\mu'_j}(\boldsymbol{k}'_{\mathrm{C}})[\epsilon_{\mu_j}(\boldsymbol{k}_{\mathrm{C}})\cdot q] - \epsilon^{\mu}_{\mu_j}(\boldsymbol{k}_{\mathrm{C}})[\epsilon^{*}_{\mu'_j}(\boldsymbol{k}'_{\mathrm{C}})\cdot q]\right\} \\
&\qquad+\frac{m^2_{\mathrm{C}}}{K_{\mathrm{e}}\cdot K_{\mathrm{C}}}\left\{ b_1(Q^2,k)\epsilon^{*}_{\mu'_j}(\boldsymbol{k}'_{\mathrm{C}})\cdot\epsilon_{\mu_j}(\boldsymbol{k}_{\mathrm{C}}) + b_2(Q^2,k)\frac{[\epsilon^{*}_{\mu'_j}(\boldsymbol{k}'_{\mathrm{C}})\cdot q][\epsilon_{\mu_j}(\boldsymbol{k}_{\mathrm{C}})\cdot q]}{m^2_{\mathrm{C}}} \right. \\
&\qquad\quad+b_3(Q^2,k)\,4m^2_{\mathrm{C}}\frac{[\epsilon^{*}_{\mu'_j}(\boldsymbol{k}'_{\mathrm{C}})\cdot K_{\mathrm{e}}][\epsilon_{\mu_j}(\boldsymbol{k}_{\mathrm{C}})\cdot K_{\mathrm{e}}]}{(K_{\mathrm{e}}\cdot K_{\mathrm{C}})^2} \\
&\qquad\quad\left.+b_4(Q^2,k)\frac{[\epsilon^{*}_{\mu'_j}(\boldsymbol{k}'_{\mathrm{C}})\cdot q][\epsilon_{\mu_j}(\boldsymbol{k}_{\mathrm{C}})\cdot K_{\mathrm{e}}] - [\epsilon^{*}_{\mu'_j}(\boldsymbol{k}'_{\mathrm{C}})\cdot K_{\mathrm{e}}][\epsilon_{\mu_j}(\boldsymbol{k}_{\mathrm{C}})\cdot q]}{K_{\mathrm{e}}\cdot K_{\mathrm{C}}}\right\} K^{\mu}_{\mathrm{e}} \\
&\qquad+b_5(Q^2,k)\frac{[\epsilon^{*}_{\mu'_j}(\boldsymbol{k}'_{\mathrm{C}})\cdot K_{\mathrm{e}}][\epsilon_{\mu_j}(\boldsymbol{k}_{\mathrm{C}})\cdot K_{\mathrm{e}}]}{(K_{\mathrm{e}}\cdot K_{\mathrm{C}})^2}4m^2_{\mathrm{C}}K^{\mu}_{\mathrm{C}} \\
&\qquad+b_6(Q^2,k)\frac{[\epsilon^{*}_{\mu'_j}(\boldsymbol{k}'_{\mathrm{C}})\cdot q][\epsilon_{\mu_j}(\boldsymbol{k}_{\mathrm{C}})\cdot K_{\mathrm{e}}] - [\epsilon^{*}_{\mu'_j}(\boldsymbol{k}'_{\mathrm{C}})\cdot K_{\mathrm{e}}][\epsilon_{\mu_j}(\boldsymbol{k}_{\mathrm{C}})\cdot q]}{K_{\mathrm{e}}\cdot K_{\mathrm{C}}}K^{\mu}_{\mathrm{C}} \\
&\qquad+b_7(Q^2,k)\,2m^2_{\mathrm{C}}\frac{\epsilon^{\mu *}_{\mu'_j}(\boldsymbol{k}'_{\mathrm{C}})[\epsilon_{\mu_j}(\boldsymbol{k}_{\mathrm{C}})\cdot K_{\mathrm{e}}] + \epsilon^{\mu}_{\mu_j}(\boldsymbol{k}_{\mathrm{C}})[\epsilon^{*}_{\mu'_j}(\boldsymbol{k}'_{\mathrm{C}})\cdot K_{\mathrm{e}}]}{K_{\mathrm{e}}\cdot K_{\mathrm{C}}} \\
&\qquad+b_8(Q^2,k)\frac{[\epsilon^{*}_{\mu'_j}(\boldsymbol{k}'_{\mathrm{C}})\cdot q][\epsilon_{\mu_j}(\boldsymbol{k}_{\mathrm{C}})\cdot K_{\mathrm{e}}] + [\epsilon^{*}_{\mu'_j}(\boldsymbol{k}'_{\mathrm{C}})\cdot K_{\mathrm{e}}][\epsilon_{\mu_j}(\boldsymbol{k}_{\mathrm{C}})\cdot q]}{K_{\mathrm{e}}\cdot K_{\mathrm{C}}}q^{\mu}\,, \qquad (5.9)
\end{aligned}
$$

where we have used Eq. (B.32). The covariant structure of the current tensor $J_{\mathrm{V}}(\boldsymbol{k}'_{\mathrm{C}};\boldsymbol{k}_{\mathrm{C}};K_{\mathrm{e}})^{\mu}_{\sigma\tau}$ can be obtained from $J_{\mathrm{V}}(\boldsymbol{p}'_{\mathrm{C}};\boldsymbol{p}_{\mathrm{C}};P_{\mathrm{e}})^{\mu}_{\sigma\tau}$ with the help of the canonical boosts $B_{\mathrm{c}}(-\boldsymbol{V})$:

$$
\begin{aligned}
&\frac{1}{|\,\mathrm{e}\,|}\,J_{\mathrm{V}}(\boldsymbol{k}'_{\mathrm{C}};\boldsymbol{k}_{\mathrm{C}};K_{\mathrm{e}})^{\mu}_{\sigma\tau} \\
&\quad= \frac{1}{|\,\mathrm{e}\,|}\,B_{\mathrm{c}}(-\boldsymbol{V})_{\sigma}{}^{\lambda}B_{\mathrm{c}}(-\boldsymbol{V})_{\tau}{}^{\rho}B_{\mathrm{c}}(-\boldsymbol{V})^{\mu}{}_{\nu}J_{\mathrm{V}}(\boldsymbol{p}'_{\mathrm{C}};\boldsymbol{p}_{\mathrm{C}};P_{\mathrm{e}})^{\nu}_{\lambda\rho} \\
&\quad= \left\{f_1(Q^2,k)\mathrm{g}_{\sigma\tau} + f_2(Q^2,k)\frac{q_\sigma q_\tau}{2m^2_{\mathrm{C}}}\right\}K^{\mu}_{\mathrm{C}} + g_{\mathrm{M}}(Q^2,k)\left\{\mathrm{g}^{\mu}_{\sigma}q_\tau - \mathrm{g}^{\mu}_{\tau}q_\sigma\right\} \\
&\qquad+\left\{b_1(Q^2,k)\mathrm{g}_{\sigma\tau} + b_2(Q^2,k)\frac{q_\sigma q_\tau}{m^2_{\mathrm{C}}} + b_3(Q^2,k)4m^2_{\mathrm{C}}\frac{K_{\mathrm{e}\sigma}K_{\mathrm{e}\tau}}{(K_{\mathrm{e}}\cdot K_{\mathrm{C}})^2}\right. \\
&\qquad\quad\left.+b_4(Q^2,k)\frac{K_{\mathrm{e}\tau}q_\sigma - K_{\mathrm{e}\sigma}q_\tau}{K_{\mathrm{e}}\cdot K_{\mathrm{C}}}\right\}\frac{m^2_{\mathrm{C}}}{K_{\mathrm{e}}\cdot K_{\mathrm{C}}}K^{\mu}_{\mathrm{e}} +
\end{aligned}
$$

$$+b_5(Q^2,k)\frac{K_{\mathrm{e}\sigma}K_{\mathrm{e}\tau}}{(K_\mathrm{e}\cdot K_\mathrm{C})^2}\,4m_\mathrm{C}^2K_\mathrm{C}^\mu+b_6(Q^2,k)\frac{K_{\mathrm{e}\tau}q_\sigma-K_{\mathrm{e}\sigma}q_\tau}{K_\mathrm{e}\cdot K_\mathrm{C}}K_\mathrm{C}^\mu$$
$$+b_7(Q^2,k)\,2m_\mathrm{C}^2\frac{\mathrm{g}_\sigma^\mu K_{\mathrm{e}\tau}+\mathrm{g}_\tau^\mu K_{\mathrm{e}\sigma}}{K_\mathrm{e}\cdot K_\mathrm{C}}+b_8(Q^2,k)\frac{q_\sigma K_{\mathrm{e}\tau}+q_\tau K_{\mathrm{e}\sigma}}{K_\mathrm{e}\cdot K_\mathrm{C}}\,q^\mu\,, \tag{5.10}$$

where we have used Eq. (A.6).

5.3 Extracting the Form Factors

The aim of this section is to extract the physical form factors defined by Eqs. (5.6) and (5.9) from the corresponding expressions for the bound-state currents, Eqs. (4.31) and (4.37), respectively.

5.3.1 Kinematics

In order to find explicit expressions for the form factors as overlap integrals of the bound-state wave functions we have to specify our kinematics. For convenience (without loss of generality) we choose the (1,3)-plane as the scattering plane and the incoming bound-state three-momenta and the momentum transfer as [Fuc07, BSFK09]

$$\boldsymbol{k}_\mathrm{C}=\begin{pmatrix}-\frac{Q}{2}\\ 0\\ \sqrt{k^2-\frac{Q^2}{4}}\end{pmatrix},\quad \boldsymbol{q}=\begin{pmatrix}Q\\ 0\\ 0\end{pmatrix},\qquad \boldsymbol{k}'_\mathrm{C}=\boldsymbol{k}_\mathrm{C}+\boldsymbol{q}\,, \tag{5.11}$$

with k given by Eq. (5.2). It should be noted that Q is restricted by $Q<2k$ in order to keep the bound-state momenta real. In the following we will consider two particular choices of frames, which are characterized by the value of k: the standard Breit frame with $k=Q/2$ and the *infinite-momentum frame* with $k\to\infty$.

Limit $k\to\infty$

In the infinite-momentum frame, where $k\to\infty$, we have for the incoming bound-state and electron four-momenta

$$k_\mathrm{C}^\mu\overset{k\to\infty}{\longrightarrow}\begin{pmatrix}k\\ -\frac{Q}{2}\\ 0\\ k\end{pmatrix}^\mu\quad\text{and}\quad k_\mathrm{e}^\mu\overset{k\to\infty}{\longrightarrow}\begin{pmatrix}k\\ \frac{Q}{2}\\ 0\\ -k\end{pmatrix}^\mu, \tag{5.12}$$

respectively. For the internal cluster center-of-mass momentum and the free invariant cluster mass we find in this limit [Fuc07, BSFK09]

$$\tilde{\boldsymbol{k}}_1\overset{k\to\infty}{\longrightarrow}\begin{pmatrix}\tilde{k}_1^{1\prime}+\left(\frac{\tilde{k}_1^{3\prime}}{m'_{12}}-\frac{1}{2}\right)Q\\ \tilde{k}_1^{2\prime}\\ \tilde{k}_1^{3\prime}\frac{m_{12}}{m'_{12}}\end{pmatrix}, \tag{5.13}$$

and

$$m_{12} \overset{k\to\infty}{\longrightarrow} \sqrt{m_{12}'^2 - \frac{4\tilde{k}_1^{1\prime} m_{12}'}{2\tilde{k}_1^{3\prime} + m_{12}'} Q + \frac{\left(m_{12}' - 2\tilde{k}_1^{3\prime}\right)}{2\tilde{k}_1^{3\prime} + m_{12}'} Q^2}\,, \tag{5.14}$$

respectively. Further, the kinematical factors of the microscopic bound-state current, Eq. (4.26), become

$$\sqrt{k_{\mathrm{C}}^0 k_{\mathrm{C}}'^0} \overset{k\to\infty}{\longrightarrow} k \quad \text{and} \quad \sqrt{\frac{k_{12}^0}{k_{12}'^0}} \overset{k\to\infty}{\longrightarrow} 1\,. \tag{5.15}$$

Finally, we give the expression for the constituent current over k_i^0 expanded in a series around $k = \infty$ and keeping only terms up to $\mathcal{O}(1/k)$:

$$\begin{aligned}
&\frac{J_i^\mu\left(\boldsymbol{k}_i', \mu_i'; \boldsymbol{k}_i, \mu_i\right)}{k_i^0} \\
&\quad = \; |\,\mathrm{e}\,|\, F_1^i(Q_i^2) \Big[\delta_{\mu_i \mu_i'} \\
&\qquad \times \left(2, \frac{4m_{12}'\tilde{k}_i'^1 - m_{12}'Q_i + 2\tilde{k}_i'^3 Q_i}{k(m_{12}' + 2\tilde{k}_i'^3)}, -\frac{2m_{12}'(-2\tilde{k}_i'^2 - 2\mu_i\,\mathrm{i}\,Q_i)}{k(m_{12}' + 2\tilde{k}_i'^3)}, 2\right)^\mu \\
&\qquad + \delta_{\mu_i' -\mu_i} \left(-\frac{2m_{12}'Q_i}{k(m_{12}' + 2\tilde{k}_i'^3)}, 0, 0, -\frac{2m_{12}'Q_i}{k(m_{12}' + 2\tilde{k}_i'^3)}\right)^\mu\Big] \\
&\quad +(-1)^{\mu_i - \frac{1}{2}} \sqrt{\tau}\, |\,\mathrm{e}\,|\, F_2^i(Q_i^2) \Bigg[\frac{\delta_{\mu_i' \mu_i}}{k(m_{12}' + 2\tilde{k}_i'^3)} \\
&\qquad \times \Big(-2\mathrm{i}\, m_{12}'(-2\tilde{k}_i'^2 - 2\mu_i\,\mathrm{i}\,Q_i), 0, 4\mathrm{i}\, m_i m_{12}', -2(-2\mathrm{i}\, m_{12}'\tilde{k}_i'^2 + 2\mu_i m_{12}' Q_i)\Big)^\mu \\
&\qquad +\delta_{\mu_i' -\mu_i} \left(2, \frac{4m_{12}'\tilde{k}_i'^1 - m_{12}'Q_i + 2\tilde{k}_i'^3 Q_i}{k(m_{12}' + 2\tilde{k}_i'^3)}, \frac{4m_{12}'\tilde{k}_i'^2}{k(m_{12}' + 2\tilde{k}_i'^3)}, 2\right)^\mu\Bigg] \\
&\quad +\mathcal{O}(1/k^2)
\end{aligned} \tag{5.16}$$

with $i = \mathrm{q}, \mathrm{N}$. In the limit $k \to \infty$ the above expression becomes

$$\begin{aligned}
&\frac{J_i^\mu\left(\boldsymbol{k}_i', \mu_i'; \boldsymbol{k}_i, \mu_i\right)}{k_i^0} \\
&\quad \overset{k\to\infty}{\longrightarrow} \; |\,\mathrm{e}\,|\, \Big[F_1^i(Q^2)\delta_{\mu_i' \mu_i} + (-1)^{\mu_i - \frac{1}{2}}\sqrt{\tau} F_2^i(Q^2)\delta_{\mu_i' -\mu_i}\Big] (2, 0, 0, 2)^\mu\,,
\end{aligned} \tag{5.17}$$

with $\tau = Q^2/(4m_i^2)$. In addition, we note that in the limit $k \to \infty$ the four-momentum transfer to the (active) constituent, in particular its zero-component, goes over to the four-momentum transfer to the cluster:

$$q_i^\mu = k_i'^\mu - k_i^\mu \overset{k\to\infty}{\longrightarrow} q^\mu = k_{\mathrm{C}}'^\mu - k_{\mathrm{C}}^\mu\,. \tag{5.18}$$

5.3.2 Pseudoscalar Bound States

Coupled Equations for the Form Factors

The analysis in Sec. 5.2.1 revealed that the current for pseudoscalar bound systems $J_{\mathrm{PS}}^\mu(\boldsymbol{k}_{\mathrm{C}}'; \boldsymbol{k}_{\mathrm{C}}; K_{\mathrm{e}})$ has 2 vanishing components due to current conservation and covariance. With the chosen kinematics given in Sec. 5.3.1 the two, in general non-vanishing components are $J^0_{\mathrm{PS}}(\boldsymbol{k}'_{\mathrm{C}};\boldsymbol{k}_{\mathrm{C}};K_{\mathrm{e}})$ and $J^3_{\mathrm{PS}}(\boldsymbol{k}'_{\mathrm{C}};\boldsymbol{k}_{\mathrm{C}};K_{\mathrm{e}})$. This can be easily seen from Eq. (5.6) by inserting (5.11) for the momenta. Therefore, we have 2 coupled equations for the form factors:

$$\begin{aligned}
2\sqrt{k^2+m_{\mathrm{C}}^2}f(Q^2,k)+2\sqrt{k^2+m_{\mathrm{e}}^2}\,\tilde{b}(Q^2,k) &= \frac{1}{|\,\mathrm{e}\,|}J^0_{\mathrm{PS}}(\boldsymbol{k}'_{\mathrm{C}};\boldsymbol{k}_{\mathrm{C}};K_{\mathrm{e}})\,,\\
2\sqrt{k^2-\frac{Q^2}{4}}f(Q^2,k)-2\sqrt{k^2-\frac{Q^2}{4}}\tilde{b}(Q^2,k) &= \frac{1}{|\,\mathrm{e}\,|}J^3_{\mathrm{PS}}(\boldsymbol{k}'_{\mathrm{C}};\boldsymbol{k}_{\mathrm{C}};K_{\mathrm{e}})\,.
\end{aligned} \tag{5.19}$$

Solving for the form factors we obtain the expressions

$$f(Q^2,k) = \frac{1}{|\,\mathrm{e}\,|\left(1+\frac{\sqrt{k^2+m_{\mathrm{C}}^2}}{\sqrt{k^2+m_{\mathrm{e}}^2}}\right)}\left(\frac{J^0_{\mathrm{PS}}(\boldsymbol{k}'_{\mathrm{C}};\boldsymbol{k}_{\mathrm{C}};K_{\mathrm{e}})}{2\sqrt{k^2+m_{\mathrm{e}}^2}}+\frac{J^3_{\mathrm{PS}}(\boldsymbol{k}'_{\mathrm{C}};\boldsymbol{k}_{\mathrm{C}};K_{\mathrm{e}})}{2\sqrt{k^2-\frac{Q^2}{4}}}\right), \tag{5.20}$$

$$\tilde{b}(Q^2,k) = \frac{1}{|\,\mathrm{e}\,|\left(1+\frac{\sqrt{k^2+m_{\mathrm{e}}^2}}{\sqrt{k^2+m_{\mathrm{C}}^2}}\right)}\left(\frac{J^0_{\mathrm{PS}}(\boldsymbol{k}'_{\mathrm{C}};\boldsymbol{k}_{\mathrm{C}};K_{\mathrm{e}})}{2\sqrt{k^2+m_{\mathrm{C}}^2}}-\frac{J^3_{\mathrm{PS}}(\boldsymbol{k}'_{\mathrm{C}};\boldsymbol{k}_{\mathrm{C}};K_{\mathrm{e}})}{2\sqrt{k^2-\frac{Q^2}{4}}}\right). \tag{5.21}$$

A numerical analysis of these expressions, which will be presented in Sec. 7.1, confirms that both, the physical form factor f and the spurious form factor $\tilde{b}$ depend indeed on k. However, this k-dependence of f vanishes rather quickly with increasing k (or equivalently increasing invariant bound-state-electron mass $M^{(\prime)}_{\mathrm{Ce}}$ or increasing Mandelstam s). At the same time the spurious form factor $\tilde{b}$ is seen to vanish. It is thus suggestive to take the limit $k\to\infty$ to get a sensible result for the physical form factor f that only depends on Q^2. In addition, this limit removes all (unwanted) spurious contributions in the current of (5.3) due to the vanishing of $\tilde{b}$ [BKS11a, BKS11b].

Limit $k\to\infty$

Before we examine the analytic expressions for the form factors f and $\tilde{b}$, Eqs. (5.20) and (5.21), in the limit $k\to\infty$, we note that the point-like constituent current over k_i^0 becomes, for $k\to\infty$, equal to $|\,\mathrm{e}\,|\,\delta_{\mu'_i\mu_i}(2,0,0,2)^\mu$, as can be seen from Eq. (5.17). Thus, for point-like constituents, the only expression occurring under the integral of the pseudoscalar bound-state current, Eq. (4.31), that has not yet been investigated in this limit is the sum over the Wigner D-function $D^{\frac{1}{2}}_{\mu_1\mu'_1}$ multiplied by the constituent current. Evidently, this product becomes the trace over the Wigner D-function and is given with our standard kinematics, Eq. (5.11), by[3] [BSFK09]

$$
\begin{aligned}
&\frac{1}{2}\sum_{\mu_1} D^{\frac{1}{2}}_{\mu_1\mu_1}\left[\underline{B}_{\mathrm{c}}\left(\boldsymbol{w}_1\right)\sigma_\tau \begin{pmatrix} w^0_{12} \\ -\boldsymbol{w}_{12} \end{pmatrix}^{\tau} \underline{w}_2\,\sigma_\nu \begin{pmatrix} w'^0_{12} \\ -\boldsymbol{w}'_{12} \end{pmatrix}^{\nu} \underline{B}_{\mathrm{c}}\left(\boldsymbol{w}'_1\right)\right] \\
&\xrightarrow{k\to\infty} \frac{m'_{12}}{m_{12}} - \frac{2\tilde{k}'^{1}_{1}\,Q}{m_{12}(m'_{12}+2\tilde{k}'^{3}_{1})} \\
&=: \mathcal{S}\,. \qquad (5.22)
\end{aligned}
$$

Note that the factor 1/2 in front comes from the two Clebsch-Gordan coefficients that have been included in $D^{\frac{1}{2}}_{\mu_1\mu'_1}$, cf. Eq. (4.30). $\mathcal{S}$ of Eq. (5.22) is obviously a finite expression. Eq. (5.17) together with the expressions for the kinematical factors, Eqs. (5.15) and (5.22), give rise to the conclusion that

$$
\begin{aligned}
&\lim_{k\to\infty} J^{\mu}_{\mathrm{PS}}(\boldsymbol{k}'_{\mathrm{C}};\boldsymbol{k}_{\mathrm{C}};K_{\mathrm{e}}) &=:& \ |\,\mathrm{e}\,|\,F(Q^2)\lim_{k\to\infty} K^{\mu}_{\mathrm{C}} \qquad (5.23)\\
\Rightarrow\ &\lim_{k\to\infty} J^{0}_{\mathrm{PS}}(\boldsymbol{k}'_{\mathrm{C}};\boldsymbol{k}_{\mathrm{C}};K_{\mathrm{e}}) &=& \ \lim_{k\to\infty} J^{3}_{\mathrm{PS}}(\boldsymbol{k}'_{\mathrm{C}};\boldsymbol{k}_{\mathrm{C}};K_{\mathrm{e}})\,. \qquad (5.24)
\end{aligned}
$$

We see that the microscopic current factorizes explicitly into the covariant K^{μ}_{C} times a Q^2-dependent integral which can be identified as the physical form factor of the pseudoscalar bound system. We finally end up with a quite simple analytic expression for F defined by Eq. (5.20) for $k \to \infty$ (or equivalently by Eq. (5.23)) [BSFK09]:

$$
\begin{aligned}
F(Q^2) &:= \lim_{k\to\infty} f(Q^2,k) \\
&= \frac{1}{|\,\mathrm{e}\,|}\lim_{k\to\infty}\frac{1}{2k} J^{0}_{\mathrm{PS}}(\boldsymbol{k}'_{\mathrm{C}};\boldsymbol{k}_{\mathrm{C}};K_{\mathrm{e}}) \\
&= \frac{1}{4\pi}\int \mathrm{d}^3\tilde{k}'_1 \sqrt{\frac{m_{12}}{m'_{12}}}\,\mathcal{S}\,u^{*}_{n0}\left(\tilde{k}'_1\right)u_{n0}\left(\tilde{k}_1\right). \qquad (5.25)
\end{aligned}
$$

This expression is clearly independent of k. Further, we note that $F(Q^2)$ is independent of the reference frame since our Bakamjian-Thomas type approach ensures Poincaré invariance. The integrand on the right-hand side of Eq. (5.25) depends only on the momentum transfer Q and the internal constituent momentum $\tilde{\boldsymbol{k}}'_1$, which is integrated over. Details of the dynamics enter solely via the form of the bound-state wave function $u_{n0}\left(\tilde{k}_1\right)$ and not via the mass of the bound cluster. What we have achieved with Eq. (5.25) is an impulse approximation to the electromagnetic bound-state form factor. In the limit $k \to \infty$ the whole photon momentum is transferred to one of the constituents due to Eq. (5.18), whereas the other one acts as a spectator. It should also be noted that the constituents' spins described by the spin-rotation factor $\mathcal{S}$ have a substantial effect on the electromagnetic form factor over nearly the whole momentum-transfer range and thus must not be neglected [BSFK09].

The spurious form factor vanishes in the limit $k \to \infty$ [BKS11a, BKS11b]:

$$
\lim_{k\to\infty} \tilde{b}(Q^2,k) = 0\,. \qquad (5.26)
$$

---

[3] Due to the complexity of the left-hand side this equation has been computed using MATHEMATICA©.

Furthermore, the whole spurious part of the current is seen to vanish in the limit $k \to \infty$:

$$\lim_{k\to\infty} \tilde{b}(Q^2, k) K_{\rm e}^{\mu} = 0\,. \tag{5.27}$$

Thus the electromagnetic current for a pseudoscalar bound system $J^{\mu}_{\rm PS}(\boldsymbol{p}'_{\rm C}; \boldsymbol{p}_{\rm C})$, Eq. (4.33), exhibits the correct cluster-separability properties in the limit $k \to \infty$. We can also turn this around and say that we have found a reference frame for the $\gamma^* {\rm C} \to {\rm C}$ subprocess in which a one-body constituent current already provides the correct cluster-separability properties for the electromagnetic current of a pseudoscalar bound system [BSFK09].

Projection Vector

Another prescription to extract the form factor is similar to the one proposed in Refs. [KS94, CDKM98]. Contracting the pseudoscalar bound-state current with the four-vector $K_{\rm e}^{\mu}/K_{\rm C} \cdot K_{\rm e}$ in the limit $k \to \infty$ projects out the form factor:

$$F(Q^2) = \frac{1}{|\,{\rm e}\,|} \lim_{k\to\infty} \frac{K_{{\rm e}\mu}}{K_{\rm C} \cdot K_{\rm e}} J^{\mu}_{\rm PS}(\boldsymbol{k}'_{\rm C}; \boldsymbol{k}_{\rm C}; K_{\rm e})\,. \tag{5.28}$$

This prescription for the extraction of the form factors is equivalent to solving the system of equations for the form factors. Both results for $F(Q^2)$, Eqs. (5.28) and (5.25), coincide.

Physical Current

With a prescription for eliminating the unphysical contributions we are now able to define a physical covariant current of a pseudoscalar bound system that satisfies all required properties including macrocausality. It is given by

$$I^{\mu}_{\rm PS}(\boldsymbol{V}) := B_{\rm c}(\boldsymbol{V})^{\mu}_{\ \nu} \lim_{k\to\infty} J^{\nu}_{\rm PS}(\boldsymbol{k}'_{\rm C}; \boldsymbol{k}_{\rm C}; K_{\rm e})\,. \tag{5.29}$$

Comparison with the Standard Front-Form Approach

We extract the electromagnetic form factor of a pseudoscalar bound system in the limit $k \equiv |\boldsymbol{k}_{\rm C}| \to \infty$. It means that we consider the subprocess where the photon is absorbed or emitted by the the bound state in the infinite-momentum frame of the bound state [BSFK09]. This offers the possibility of making a direct comparison with form factor analyses done in the front form of relativistic dynamics. The $k \to \infty$ limit with our standard kinematics, as chosen in Eq. (5.11), implies in particular that we work in a reference frame in which the plus component of the four-momentum transfer $q^+ := q^0 + q^3$ vanishes. $q^+ = 0$ frames are also popular in the form-factor studies in front form [CCP88, KP91, Sim02, CP05]. One reason is that the impulse approximation can be formulated consistently in any $q^+ = 0$ frame (for the plus component of the current operator) [KP91]. The other benefit is that, so-called, *Z-graphs* are suppressed in such frames [Sim02].

Our point-form calculation can be related to front form results by an appropriate change of variables. To show this relation we define the longitudinal momentum fractions z as

$$z^{(\prime)} := \frac{\tilde{k}_1^{3(\prime)}}{m_{12}^{(\prime)}} + \frac{1}{2} \tag{5.30}$$

and introduce the short-hand notation

$$\boldsymbol{k}_\perp^{(\prime)} := \begin{pmatrix} \tilde{k}_1^{1(\prime)} \\ \tilde{k}_1^{2(\prime)} \end{pmatrix} \tag{5.31}$$

for the intrinsic transverse momentum of the active incoming (outgoing) constituent. From Eq. (5.13) we infer that

$$z = z' \quad \text{and} \quad \boldsymbol{k}'_\perp = \boldsymbol{k}_\perp + (1-z)\,\boldsymbol{q}_\perp \quad \text{with} \quad \boldsymbol{q}_\perp = \begin{pmatrix} Q \\ 0 \end{pmatrix} . \tag{5.32}$$

The free invariant mass of the incoming (outgoing) 12-system can then be written as

$$m_{12}^{(\prime)} = \sqrt{\frac{m^2 + \boldsymbol{k}_\perp^{(\prime)2}}{z(1-z)}} . \tag{5.33}$$

With these relations the Jacobian for the variable transformation $\{\tilde{k}_1^{1\prime}, \tilde{k}_1^{2\prime}, \tilde{k}_1^{3\prime}\} \to \{z, k_\perp^1, k_\perp^2\}$ becomes

$$\frac{\partial(\tilde{k}_1^{1\prime}, \tilde{k}_1^{2\prime}, \tilde{k}_1^{3\prime})}{\partial(z, k_\perp^1, k_\perp^2)} = \frac{m'_{12}}{4z(1-z)} . \tag{5.34}$$

Then the integral for the electromagnetic form factor takes on the form [BSFK09]

$$F(Q^2) = \frac{1}{4\pi} \int_0^1 \mathrm{d}z \int_{\mathbb{R}^2} \mathrm{d}^2 k_\perp \frac{\sqrt{m_{12}\, m'_{12}}}{4z(1-z)} \mathcal{M}\, u_{n0}^*(\tilde{k}'_1)\, u_{n0}(\tilde{k}_1) . \tag{5.35}$$

The argument of the wave functions is easily expressed in terms of z and $\boldsymbol{k}_\perp$ if one uses $\tilde{\boldsymbol{k}}_1^{(\prime)2} = m^2 + m_{12}^{(\prime)\,2}/4$ and Eq. (5.33). By the change of variables the spin-rotation factor $\mathcal{S}$, cf. Eq. (5.22), goes over into the Melosh-rotation factor of Ref. [CCP88]

$$\mathcal{M} = \frac{m_{12}}{m'_{12}} \left(1 + \frac{(1-z)\,(\boldsymbol{q}_\perp \cdot \boldsymbol{k}_\perp)}{m^2 + \boldsymbol{k}_\perp^2} \right) . \tag{5.36}$$

$\mathcal{S}$ and $\mathcal{M}$ describe the effect of the constituents' spin onto the electromagnetic form factor in point form and in front form, respectively. Eqs. (5.35) and (5.36) are identical to the corresponding formulae in Refs. [CCP88, Sim02]. This is a remarkable result. Starting from two different forms of relativistic dynamics and applying completely different procedures to identify the electromagnetic form factor of a pseudoscalar bound system the outcome is the same. It means that relativity is treated in an equivalent way and the physical ingredients are alike. Since the infinite-momentum frame we use is just a particular $q^+ = 0$ frame, Z-graph contributions to the electromagnetic form factor are also suppressed in our point-form approach. This is a welcome feature, because Z-graphs can play a significant role in $q^+ \neq 0$ frames [Sim02] and one should have control on them when form-factor predictions are compared with experiment.

Comparison with Covariant Light-Front Dynamics

The above standard front form of relativistic dynamics, which is characterized by the light-front plane $x^0 + x^3 = 0$ (cf. Sec. 3.2) is not manifestly (explicitly) covariant due to the dynamic nature of some Lorentz transformations that change the orientation of the light front. This problem can, however, be overcome by introducing an arbitrary light-like four-vector ω^μ that defines the orientation of the light front which is then described by the equality $\omega \cdot x = 0$. Such an explicit covariant light-front approach has been formulated in the works of Refs. [KS94, CDKM98]. The particular choice of $\omega = (1, 0, 0, -1)$ then corresponds to the standard (non-covariant) front-form approach.

The Lorentz structure of the current $J^\mu_{\mathrm{PS}}(\boldsymbol{k}'_{\mathrm{C}}; \boldsymbol{k}_{\mathrm{C}}; K_{\mathrm{e}})$ for a pseudoscalar bound state described by Eq. (5.3) resembles the corresponding current obtained within the covariant light-front dynamics of Refs. [KS94, CDKM98]. In these works the authors encounter a spurious (unphysical) contribution to the current which is associated with ω^μ. Their spurious contribution is comparable to our spurious contribution if ω^μ is identified with K^μ_{e}. It has already been mentioned that spurious K_{e}-dependent terms in the current of our point-form Bakamjian-Thomas approach can be traced back to the violation of cluster separability. However, by taking the limit $k \to \infty$ we can eliminate these cluster separability violating effects [BKS11a]. In the covariant light-front formalism the spurious ω-dependent contribution is rather the consequence of the most general ansatz for a current of a pseudoscalar bound-state that includes the orientation of the light front.

In the standard light front approach, i.e. $\omega = (1, 0, 0, -1)$, the electromagnetic form factor of a pseudoscalar bound state is usually extracted from matrix elements of the plus component of the current operator. Due to $\omega^+ = 0$ in the standard case, the second (spurious) part of the current proportional to ω^μ does not contribute [KS94]. Therefore, it is not surprising that standard light-front and covariant light-front dynamics give the same results for the form factor of a pseudoscalar bound-state, which is some way a special case due to the simplicity of spin-0 systems. Consequently, taking the plus component of the current to extract the form factor in the standard light-front approach plays a similar role to taking the limit $k \to \infty$ in our approach in the sense that in both cases one gets rid of the spurious contribution in the current.

Comparison with the Point-Form Spectator Model

Relativistic point-form quantum mechanics has also been applied in Ref. [WBK$^+$01, B$^+$02] to calculate electroweak baryon form factors within a constituent quark model. The strategy for the extraction of electromagnetic form factors, however, differs from the one in the present work. We apply the Bakamjian-Thomas type framework to the full electron-bound-state system in order to derive the electromagnetic bound-state current. In their works the Bakamjian-Thomas framework for the bound-state system is only used to obtain the bound-state wave function. This wave function is then plugged into an ansatz for the electromagnetic bound-state current. The ansatz is constrained by the requirements of continuity and covariance. It is shown that these constraints can be satisfied by a spectator current if not all of the photon momentum is transferred to the active constituent. The momentum transfer to the active constituent q_1 is uniquely determined by total four-momentum conservation for the $\gamma^*\mathrm{C} \to \mathrm{C}$ subprocess and by the spectator conditions. An ambiguity in defining such a spectator current, however, enters through a normalization factor which has to be introduced in order to recover the bound-state charge from the electric form factor in the limit $Q^2 \to 0$ [MCPW05]. Since both quantities,

q_1 and the normalization factor depend effectively on all quark momenta and not only on those of the active ones, the model current constructed in this way cannot be considered as a pure one-body current [MBC$^+$07]. It has therefore been termed *point-form spectator model* to distinguish it from the usual impulse approximation.

A comparison of our result for the form factor with the one of the point-form spectator model reveals that the dynamics enter into the former solely via the bound-state wave function, whereas the latter also exhibits an explicit dependence on the bound-state mass m_C. Within the point-form spectator model the eigenvalue spectrum of the mass operator is thus directly connected with the electromagnetic structure of its eigenstates [BSFK09]. We shall come back on this issue when doing a numerical comparison between both approaches.

5.3.3 Vector Bound States

Current Matrix Elements

By a numerical analysis, whose dynamical ingredients will be discussed in detail later, using the standard kinematics of Eq. (5.11) we observe that our vector bound-state current $J^\mu_\mathrm{V}(\boldsymbol{k}'_\mathrm{C}, \mu'_j; \boldsymbol{k}_\mathrm{C}, \mu_j; K_\mathrm{e})$ of Eq. (4.37) has, in general, 11 independent, non-vanishing matrix elements. They are given by (using the short-hand notation $J^\mu_\mathrm{V}(\boldsymbol{k}'_\mathrm{C}, \mu'_j; \boldsymbol{k}_\mathrm{C}, \mu_j; K_\mathrm{e}) \equiv J^\mu_\mathrm{V}(\mu'_j, \mu_j)$):

$$\begin{array}{l} J^0_\mathrm{V}(1,-1)\,, \quad J^3_\mathrm{V}(1,-1)\,, \quad J^0_\mathrm{V}(0,0)\,, \quad J^3_\mathrm{V}(0,0)\,, \quad J^0_\mathrm{V}(1,0)\,, \quad J^1_\mathrm{V}(1,0)\,, \\ J^2_\mathrm{V}(1,0)\,, \quad J^3_\mathrm{V}(1,0)\,, \quad J^0_\mathrm{V}(1,1)\,, \quad J^2_\mathrm{V}(1,1)\,, \quad J^3_\mathrm{V}(1,1)\,. \end{array} \qquad (5.37)$$

This confirms numerically the outcome of the formal analysis in Sec. 5.2.2. Note that the remaining non-vanishing matrix elements are related to the above ones by the following relations:

$$J^0_\mathrm{V}(1,-1) = J^0_\mathrm{V}(-1,1)\,, \qquad (5.38)$$

$$J^3_\mathrm{V}(1,-1) = J^3_\mathrm{V}(-1,1)\,, \qquad (5.39)$$

$$J^0_\mathrm{V}(1,1) = J^0_\mathrm{V}(-1,-1)\,, \qquad (5.40)$$

$$J^3_\mathrm{V}(1,1) = J^3_\mathrm{V}(-1,-1)\,, \qquad (5.41)$$

$$J^2_\mathrm{V}(1,1) = -J^2_\mathrm{V}(-1,-1)\,, \qquad (5.42)$$

$$J^0_\mathrm{V}(1,0) = -J^0_\mathrm{V}(-1,0) = J^0_\mathrm{V}(0,-1) = -J^0_\mathrm{V}(0,1)\,, \qquad (5.43)$$

$$J^3_\mathrm{V}(1,0) = -J^3_\mathrm{V}(-1,0) = J^3_\mathrm{V}(0,-1) = -J^3_\mathrm{V}(0,1)\,, \qquad (5.44)$$

$$J^1_\mathrm{V}(1,0) = -J^1_\mathrm{V}(-1,0) = J^1_\mathrm{V}(0,1) = -J^1_\mathrm{V}(0,1)\,, \qquad (5.45)$$

$$J^2_\mathrm{V}(1,0) = J^2_\mathrm{V}(-1,0) = -J^2_\mathrm{V}(0,1) = -J^2_\mathrm{V}(0,-1)\,. \qquad (5.46)$$

Limit $k \to \infty$

Of the 11 form factors only the 3 physical form factors f_1, f_2 and g_M are of interest. We extract them from Eq. (4.37) by using the decomposition (5.9). As in the pseudoscalar case, we take the limit $k \to \infty$ where the form factors become independent of k. Furthermore, using our standard kinematics, we observe that the zeroth and third component of the current become identical in this limit, i.e.

$$J^0_{\mu'_j \mu_j} := \lim_{k\to\infty} J^0_\mathrm{V}(\mu'_j, \mu_j) = \lim_{k\to\infty} J^3_\mathrm{V}(\mu'_j, \mu_j) = J^3_{\mu'_j \mu_j}\,, \qquad (5.47)$$

which reduces the number of independent matrix elements from 11 to 7. This means, however, that 4 of the 8 spurious contributions cannot be eliminated by simply taking the limit $k \to \infty$. This complication occurs due to the complexity of spin-1 bound systems as compared to the previous spin-0 case. Nonetheless, a careful analysis (cf. App. F.1) of the covariant structure of the current reveals that the 3 current matrix elements J^0_{11}, J^0_{1-1} and J^2_{11} do not contain leading order spurious contributions (for a similar analysis in the light-front formalism see Ref. [MS02]). These "good" matrix elements are therefore appropriate for the extraction of the physical form factors, which are then given by the following rather lengthy expressions (for a derivation we refer to App. F.1):

$$\begin{aligned}
F_1(Q^2) &:= \lim_{k\to\infty} f_1(Q^2,k) \\
&= -\frac{1}{|\,\mathrm{e}\,|} \lim_{k\to\infty} \frac{1}{2k} \left[J^0_{\mathrm{V}}(1,1) + J^0_{\mathrm{V}}(1,-1)\right] \\
&= -\frac{1}{4\pi} \int \mathrm{d}^3\tilde{k}'_1 \sqrt{\frac{m_{12}}{m'_{12}}} u^*_{n0}\left(\tilde{k}'_1\right) u_{n0}\left(\tilde{k}_1\right) \\
&\quad \times \left\{ \left[F^1_1(Q^2) + F^2_1(Q^2)\right] \left(\mathcal{S}^{11}_1 + \mathcal{S}^{1-1}_1\right) \right. \\
&\qquad \left. + \sqrt{\tau} \left[F^1_2(Q^2) + F^2_2(Q^2)\right] \left(\mathcal{S}^{11}_2 + \mathcal{S}^{1-1}_2\right) \right\} , \qquad (5.48)
\end{aligned}$$

$$\begin{aligned}
F_2(Q^2) &:= \lim_{k\to\infty} f_2(Q^2,k) \\
&= -\frac{1}{|\,\mathrm{e}\,|\,\eta} \lim_{k\to\infty} \frac{1}{2k} J^0_{\mathrm{V}}(1,-1) \\
&= -\frac{1}{\eta}\frac{1}{4\pi} \int \mathrm{d}^3\tilde{k}'_1 \sqrt{\frac{m_{12}}{m'_{12}}} u^*_{n0}\left(\tilde{k}'_1\right) u_{n0}\left(\tilde{k}_1\right) \\
&\quad \times \left\{ \left[F^1_1(Q^2) + F^2_1(Q^2)\right] \mathcal{S}^{1-1}_1 + \sqrt{\tau} \left[F^1_2(Q^2) + F^2_2(Q^2)\right] \mathcal{S}^{1-1}_2 \right\} , \\
&\qquad (5.49)
\end{aligned}$$

$$\begin{aligned}
G_{\mathrm{M}}(Q^2) &:= \lim_{k\to\infty} g_{\mathrm{M}}(Q^2,k) \\
&= -\frac{\mathrm{i}}{|\,\mathrm{e}\,|\,Q} J^2_{11} \\
&= -\frac{\mathrm{i}}{Q}\frac{1}{4\pi} \int \mathrm{d}^3\tilde{k}'_1 \sqrt{\frac{m_{12}}{m'_{12}}} u^*_{n0}\left(\tilde{k}'_1\right) u_{n0}\left(\tilde{k}_1\right) \frac{m'_{12}}{(m'_{12} + 2\tilde{k}'^3_1)} \\
&\quad \times \left\{ \left[F^1_1(Q^2) + F^2_1(Q^2)\right] \left(\tilde{k}'^2_1 \mathcal{S}^{11}_1 + \frac{\mathrm{i}\,Q}{2} \mathcal{S}^{11}_3\right) \right. \\
&\qquad \left. + \sqrt{\tau} \left[F^1_2(Q^2) + F^2_2(Q^2)\right] \left(\mathrm{i}\,m\,\mathcal{S}^{11}_3 + \tilde{k}'^2_1 \mathcal{S}^{11}_2\right) \right\} , \qquad (5.50)
\end{aligned}$$

with $\eta = Q^2/(4m^2_{\mathrm{C}})$. Here $\mathcal{S}^{\mu'_j\mu_j}_1$, $\mathcal{S}^{\mu'_j\mu_j}_2$ and $\mathcal{S}^{\mu'_j\mu_j}_3$ are the spin rotation factors given by

$$\begin{aligned}
\mathcal{S}^{\mu'_j\mu_j}_1 &:= \lim_{k\to\infty} \sum D^{\frac{1}{2}}_{\mu_1\tilde{\mu}_1} \left[\underline{R}_{\mathrm{W_c}}\left(\tilde{w}_1, B_{\mathrm{c}}\left(\boldsymbol{w}_{12}\right)\right)\right] C^{1\mu_j}_{\frac{1}{2}\tilde{\mu}_1\,\frac{1}{2}\tilde{\mu}_2} \\
&\quad \times D^{\frac{1}{2}}_{\tilde{\mu}'_2\tilde{\mu}_2} \left[\underline{R}_{\mathrm{W_c}}\left(\tilde{w}_2, B^{-1}_{\mathrm{c}}\left(\boldsymbol{w}'_{12}\right) B_{\mathrm{c}}\left(\boldsymbol{w}_{12}\right)\right)\right] \\
&\quad \times C^{1\mu'_j}_{\frac{1}{2}\tilde{\mu}'_2\,\frac{1}{2}\tilde{\mu}'_1} D^{\frac{1}{2}}_{\tilde{\mu}'_1\mu_1} \left[\underline{R}_{\mathrm{W_c}}\left(w'_1, B^{-1}_{\mathrm{c}}\left(\boldsymbol{w}'_{12}\right)\right)\right] , \qquad (5.51)
\end{aligned}$$

$$\begin{aligned}
\mathcal{S}_2^{\mu'_j \mu_j} \quad := \quad & \lim_{k\to\infty} \sum (-1)^{\mu_1-\frac{1}{2}} D^{\frac{1}{2}}_{\mu_1 \tilde{\mu}_1} \left[\underline{R}_{\mathrm{W_c}} \left(\tilde{w}_1, B_{\mathrm{c}} \left(\boldsymbol{w}_{12} \right) \right) \right] C^{1\mu_j}_{\frac{1}{2}\tilde{\mu}_1 \frac{1}{2}\tilde{\mu}_2} \\
& \times D^{\frac{1}{2}}_{\tilde{\mu}'_2 \tilde{\mu}_2} \left[\underline{R}_{\mathrm{W_c}} \left(\tilde{w}_2, B_{\mathrm{c}}^{-1} \left(\boldsymbol{w}'_{12} \right) B_{\mathrm{c}} \left(\boldsymbol{w}_{12} \right) \right) \right] \\
& \times C^{1\mu'_j}_{\frac{1}{2}\tilde{\mu}'_2 \frac{1}{2}\tilde{\mu}'_1} D^{\frac{1}{2}}_{\tilde{\mu}'_1 -\mu_1} \left[\underline{R}_{\mathrm{W_c}} \left(w'_1, B_{\mathrm{c}}^{-1} \left(\boldsymbol{w}'_{12} \right) \right) \right] , \qquad (5.52) \\
\mathcal{S}_3^{\mu'_j \mu_j} \quad := \quad & \lim_{k\to\infty} \sum (-1)^{\mu_1-\frac{1}{2}} D^{\frac{1}{2}}_{\mu_1 \tilde{\mu}_1} \left[\underline{R}_{\mathrm{W_c}} \left(\tilde{w}_1, B_{\mathrm{c}} \left(\boldsymbol{w}_{12} \right) \right) \right] C^{1\mu_j}_{\frac{1}{2}\tilde{\mu}_1 \frac{1}{2}\tilde{\mu}_2} \\
& \times D^{\frac{1}{2}}_{\tilde{\mu}'_2 \tilde{\mu}_2} \left[\underline{R}_{\mathrm{W_c}} \left(\tilde{w}_2, B_{\mathrm{c}}^{-1} \left(\boldsymbol{w}'_{12} \right) B_{\mathrm{c}} \left(\boldsymbol{w}_{12} \right) \right) \right] \\
& \times C^{1\mu'_j}_{\frac{1}{2}\tilde{\mu}'_2 \frac{1}{2}\tilde{\mu}'_1} D^{\frac{1}{2}}_{\tilde{\mu}'_1 \mu_1} \left[\underline{R}_{\mathrm{W_c}} \left(w'_1, B_{\mathrm{c}}^{-1} \left(\boldsymbol{w}'_{12} \right) \right) \right] . \qquad (5.53)
\end{aligned}$$

The expressions for the form factors Eqs. (5.48)-(5.50) cannot be simplified further like in the pseudoscalar case. However, for point-like constituents like quarks with $F_1^1(Q^2) + F_1^2(Q^2) = 1$ and $F_2^1(Q^2) = F_2^2(Q^2) = 0$, they become a little bit shorter.

Projection Tensors

Another, equivalent prescription to extract the physical form factors is proposed in Refs. [KS94, CDKM98]. To this end we define appropriate tensors $F^{\sigma\tau}_{1\mu}$, $F^{\sigma\tau}_{2\mu}$ and $G^{\sigma\tau}_{\mathrm{M}\mu}$ that project out the form factors F_1, F_2 and G_{M} from the current tensor $J_{\mathrm{V}}(\boldsymbol{k}'_{\mathrm{C}}, \boldsymbol{k}_{\mathrm{C}}, K_{\mathrm{e}})^{\mu}_{\sigma\tau}$. These projection tensors are fixed by Eq. (5.10) and given by [KS94, CDKM98]

$$\begin{aligned}
F^{\sigma\tau}_{1\mu} \quad := \quad & \frac{K_{\mathrm{e}\mu}}{K_{\mathrm{e}} \cdot K_{\mathrm{C}}} \left(\mathrm{g}^{\sigma\tau} - \frac{q^\sigma q^\tau}{q^2} - \frac{K_{\mathrm{C}}^\sigma K_{\mathrm{e}}^\tau + K_{\mathrm{C}}^\tau K_{\mathrm{e}}^\sigma}{K_{\mathrm{e}} \cdot K_{\mathrm{C}}} + K_{\mathrm{C}}^2 \frac{K_{\mathrm{e}}^\sigma K_{\mathrm{e}}^\tau}{(K_{\mathrm{e}} \cdot K_{\mathrm{C}})^2} \right) , \qquad (5.54) \\
F^{\sigma\tau}_{2\mu} \quad := \quad & -\frac{K_{\mathrm{e}\mu}}{(K_{\mathrm{e}} \cdot K_{\mathrm{C}}) q^2} \left(\mathrm{g}^{\sigma\tau} - \frac{q^\sigma q^\tau}{q^2} - \frac{K_{\mathrm{C}}^\sigma K_{\mathrm{e}}^\tau + K_{\mathrm{C}}^\tau K_{\mathrm{e}}^\sigma}{K_{\mathrm{e}} \cdot K_{\mathrm{C}}} \right. \\
& \left. +4 m_{\mathrm{C}}^2 \frac{K_{\mathrm{e}}^\sigma K_{\mathrm{e}}^\tau}{(K_{\mathrm{e}} \cdot K_{\mathrm{C}})^2} - \frac{q^\sigma K_{\mathrm{e}}^\tau - q^\tau K_{\mathrm{e}}^\sigma}{K_{\mathrm{e}} \cdot K_{\mathrm{C}}} \right) , \qquad (5.55) \\
G^{\sigma\tau}_{\mathrm{M}\mu} \quad := \quad & \frac{1}{2} \left[\frac{\mathrm{g}_\mu^\sigma q^\tau - \mathrm{g}_\mu^\tau q^\sigma}{q^2} + \frac{\mathrm{g}_\mu^\sigma K_{\mathrm{e}}^\tau + \mathrm{g}_\mu^\tau K_{\mathrm{e}}^\sigma}{K_{\mathrm{e}} \cdot K_{\mathrm{C}}} \right. \\
& + \frac{K_{e\mu}}{K_e \cdot K_{\mathrm{C}}} \left(-K_{\mathrm{C}}^2 \frac{q^\sigma K_{\mathrm{e}}^\tau - q^\tau K_{\mathrm{e}}^\sigma}{(K_{\mathrm{e}} \cdot K_{\mathrm{C}}) q^2} + \frac{q^\sigma K_{\mathrm{C}}^\tau - q^\tau K_{\mathrm{C}}^\sigma}{q^2} \right. \\
& \left. +2 K_{\mathrm{C}}^2 \frac{K_{\mathrm{e}}^\sigma K_{\mathrm{e}}^\tau}{(K_{\mathrm{e}} \cdot K_{\mathrm{C}})^2} - \frac{K_{\mathrm{C}}^\sigma K_{\mathrm{e}}^\tau - K_{\mathrm{C}}^\tau K_{\mathrm{e}}^\sigma}{K_{\mathrm{e}} \cdot K_{\mathrm{C}}} \right) \\
& \left. + K_{\mathrm{C}\mu} \left(\frac{q^\sigma K_{\mathrm{e}}^\tau - q^\tau K_e^\sigma}{q^2 (K_{\mathrm{e}} \cdot K_{\mathrm{C}})} - 2 \frac{K_{\mathrm{e}}^\sigma K_{\mathrm{e}}^\tau}{(K_{\mathrm{e}} \cdot K_{\mathrm{C}})^2} \right) - q_\mu \frac{q^\sigma K_{\mathrm{e}}^\tau + q^\tau K_{\mathrm{e}}^\sigma}{(K_{\mathrm{e}} \cdot K_{\mathrm{C}}) q^2} \right] . \qquad (5.56)
\end{aligned}$$

Then the form factors are obtained by contraction of the projection tensors with the current tensor:

$$
\begin{aligned}
F_1(Q^2) &= \frac{1}{|\,\mathrm{e}\,|} \lim_{k\to\infty} F_{1\mu}^{\sigma\tau} J_{\mathrm{V}}(\boldsymbol{k}'_{\mathrm{C}}, \boldsymbol{k}_{\mathrm{C}}, K_{\mathrm{e}})^{\mu}_{\sigma\tau}\,, &(5.57)\\
F_2(Q^2) &= \frac{1}{|\,\mathrm{e}\,|} \lim_{k\to\infty} F_{2\mu}^{\sigma\tau} J_{\mathrm{V}}(\boldsymbol{k}'_{\mathrm{C}}, \boldsymbol{k}_{\mathrm{C}}, K_{\mathrm{e}})^{\mu}_{\sigma\tau}\,, &(5.58)\\
G_{\mathrm{M}}(Q^2) &= \frac{1}{|\,\mathrm{e}\,|} \lim_{k\to\infty} G_{\mathrm{M}\mu}^{\sigma\tau} J_{\mathrm{V}}(\boldsymbol{k}'_{\mathrm{C}}, \boldsymbol{k}_{\mathrm{C}}, K_{\mathrm{e}})^{\mu}_{\sigma\tau}\,. &(5.59)
\end{aligned}
$$

These are finite expressions and independent of k. It can be shown that these expressions are identical to the corresponding ones obtained from current matrix elements, Eqs. (5.48), (5.49) and (5.50) (for details, see App. F.2).

Physical Current

We have already discussed in Sec. 4.4.4 the failure of showing continuity for the bound-state current $J^{\mu}_{\mathrm{V}}(\boldsymbol{p}'_{\mathrm{C}}, \sigma'_j; \boldsymbol{p}_{\mathrm{C}}, \sigma_j; P_{\mathrm{e}})$. Actually the current is not conserved due to the spurious contributions of b_7 and b_8 (cf. Eq. (5.8)). A numerical analysis using our standard kinematics shows that these contributions do not cancel such that there is a non-vanishing contribution to $J^1_{\mathrm{V}}(1,0)$. Even in the $k \to \infty$ limit these continuity violating contributions survive. Nevertheless, with an unambiguous prescription at hand to separate the physical from the unphysical contributions we can define the physical part of the current by

$$
\begin{aligned}
&\frac{1}{|\,\mathrm{e}\,|} I^{\mu}_{\mathrm{V}}(\boldsymbol{k}'_{\mathrm{C}}, \mu'_j; \boldsymbol{k}_{\mathrm{C}}, \mu_j)\\
&:= \left[f_1(Q^2,k)\epsilon^{*}_{\mu'_j}(\boldsymbol{k}'_{\mathrm{C}}) \cdot \epsilon_{\mu_j}(\boldsymbol{k}_{\mathrm{C}}) + f_2(Q^2,k) \frac{[\epsilon^{*}_{\mu'_j}(\boldsymbol{k}'_{\mathrm{C}}) \cdot q][\epsilon_{\mu_j}(\boldsymbol{k}_{\mathrm{C}}) \cdot q]}{2m^2_{\mathrm{C}}} \right] K^{\mu}_{\mathrm{C}}\\
&\quad + g_{\mathrm{M}}(Q^2,k) \left[\epsilon^{\mu *}_{\mu'_j}(\boldsymbol{k}'_{\mathrm{C}})[\epsilon_{\mu_j}(\boldsymbol{k}_{\mathrm{C}}) \cdot q] - \epsilon^{\mu}_{\mu_j}(\boldsymbol{k}_{\mathrm{C}})[\epsilon^{*}_{\mu'_j}(\boldsymbol{k}'_{\mathrm{C}}) \cdot q] \right]. \qquad (5.60)
\end{aligned}
$$

The covariant physical current is then obtained from Eq. (4.28) by

$$
\begin{aligned}
I^{\mu}_{\mathrm{V}\sigma'_j\sigma_j}(\boldsymbol{V}) \;:=\; & B_{\mathrm{c}}(\boldsymbol{V})^{\mu}{}_{\nu} \lim_{k\to\infty} I^{\nu}_{\mathrm{V}}(\boldsymbol{k}'_{\mathrm{C}}, \mu'_j; \boldsymbol{k}_{\mathrm{C}}, \mu_j)\\
& \times D^{j*}_{\mu'_j\sigma'_j}[\underline{R}^{-1}_{\mathrm{W_c}}(w'_{\mathrm{C}}, B_{\mathrm{c}}(\boldsymbol{V}))] D^{j}_{\mu_j\sigma_j}[\underline{R}^{-1}_{\mathrm{W_c}}(w_{\mathrm{C}}, B_{\mathrm{c}}(\boldsymbol{V}))]\,.
\end{aligned}
\qquad (5.61)
$$

This current satisfies all required properties including current conservation and macrocausality.

Angular Condition

The four matrix elements $I^0_{11}, I^0_{1-1}, I^0_{10}$ and I^0_{00} with $I^{\mu}_{\mathrm{V}\sigma'_j\sigma_j}(\boldsymbol{0}) =: I^{\mu}_{\sigma'_j\sigma_j}$ depend on the 3 physical form factors and hence are not independent from each other. They satisfy the, so-called, *angular condition* (cf., e.g., Refs. [GK84, CDKM98, BJ02])

$$
(1+2\eta)I^0_{11} + I^0_{1-1} - 2\sqrt{2\eta}I^0_{10} - I^0_{00} = 0\,, \qquad (5.62)
$$

where $\eta = \frac{Q^2}{4m_\mathrm{C}^2}$. For the matrix elements of the full current $J^0_{\mu'_j \mu_j}$ including spurious contributions the angular condition is, however, not satisfied due to the spurious contributions of B_5 and B_7 (cf. Eqs. (F.32)-(F.35)):

$$\begin{aligned} &\lim_{k\to\infty} \frac{1}{2k} \left[(1+2\eta) J^0_\mathrm{V}(1,1) + J^0_\mathrm{V}(1,-1) - 2\sqrt{2\eta} J^0_\mathrm{V}(1,0) - J^0_\mathrm{V}(0,0)\right] \\ &\quad = -\,|\,\mathrm{e}\,|\, \left[B_5(Q^2) + B_7(Q^2)\right] , \end{aligned} \tag{5.63}$$

with $B_i(Q^2) := \lim_{k\to\infty} b_i(Q^2, k)$.

From Eq. (5.63) it becomes evident that the 4 matrix elements $J^0_{11}, J^0_{1-1}, J^0_{10}$ and J^0_{00} cannot be used to extract the 3 physical form factors in an unambiguous way. In the literature different triplets have been chosen to calculate the form factors [GK84, CPCK88, BH92, FSF93]. These different prescriptions lead to, in general, different results for the form factors due to non-physical contributions that enter the form factors (for a numerical and analytical comparison of different approaches, see Ref. [CGN$^+$95] and Ref. [Kar96], respectively). It is clear that if the angular condition were satisfied, different prescriptions would lead to the same form factor results [Kei94, CDKM98]. However, the magnetic form factor obtained from the plus component current would still contain the spurious form factor B_6 (for the relations between the form factors obtained from different prescriptions cf. Ref. [CDKM98]). Translating to our case this can be seen from Eqs. (F.33) and (F.34):

$$G_\mathrm{M}(Q^2) - B_6(Q^2) = \frac{1}{|\,\mathrm{e}\,|} \lim_{k\to\infty} \frac{1}{k} (J^0_\mathrm{V}(1,0) - \frac{m_\mathrm{C}\sqrt{2}}{Q} J^0_\mathrm{V}(1,1)) \, . \tag{5.64}$$

Anyway, as we shall see later by a numerical analysis, the spurious contributions, that violate continuity and the angular condition together with B_6, are relatively small.

G_C, G_Q and Elastic Scattering Observables

The charge and quadrupole form factors G_C and G_Q, respectively, are expressed through F_1, F_2 and G_M by

$$G_\mathrm{C}(Q^2) = -F_1(Q^2) - \frac{2\eta}{3}\left[F_1(Q^2) + G_\mathrm{M}(Q^2) - F_2(Q^2)(1+\eta)\right] , \tag{5.65}$$

$$G_\mathrm{Q}(Q^2) = -F_1(Q^2) - G_\mathrm{M}(Q^2) + F_2(Q^2)(1+\eta) \, . \tag{5.66}$$

These form factors have the limits given by

$$\lim_{Q^2\to 0} G_\mathrm{C}(Q^2) = 1 \, , \tag{5.67}$$

$$\lim_{Q^2\to 0} G_\mathrm{M}(Q^2) = \mu_\mathrm{V} \, , \tag{5.68}$$

$$\lim_{Q^2\to 0} G_\mathrm{Q}(Q^2) = Q_\mathrm{V} \, , \tag{5.69}$$

where $+1$ is the charge in units of the fundamental charge $|\,\mathrm{e}\,|$, μ_V the magnetic dipole moment in units of $|\,\mathrm{e}\,|/2m_\mathrm{C}$ and Q_V the electric quadrupole moment in units of $|\,\mathrm{e}\,|/m_\mathrm{C}^2$. For point-like spin-1 bound systems the magnetic dipole and the electric quadrupole moments are $\mu_\mathrm{V} = 2$ and $Q_\mathrm{V} = -1$, respectively.

The usual observables of elastic scattering of an electron by a vector bound-state are the structure functions $A(Q^2)$, $B(Q^2)$ and the tensor polarization $T_{20}(Q^2)$. $A(Q^2)$, $B(Q^2)$ are determined from the unpolarized laboratory frame differential cross section using the Rosenbluth formula. They are given in terms of form factors by

$$A(Q^2) = G_{\mathrm{C}}^2(Q^2) + \frac{8}{9}\eta^2 G_{\mathrm{Q}}^2(Q^2) + \frac{2}{3}\eta\, G_{\mathrm{M}}^2(Q^2) \tag{5.70}$$

and

$$B(Q^2) = \frac{4}{3}\eta(1+\eta)G_{\mathrm{M}}^2(Q^2)\,. \tag{5.71}$$

The observable $T_{20}(Q^2)$ for quadrupole polarization is extracted from the difference in the cross sections for target bound states having canonical spin polarizations $\mu_j = 1$ and $\mu_j = 0$. In terms of form factors it reads

$$\begin{aligned} &T_{20}(Q^2) \\ &= -\sqrt{2}\eta\,\frac{\frac{4}{9}\eta\, G_{\mathrm{Q}}^2(Q^2) + \frac{4}{3}G_{\mathrm{Q}}(Q^2)G_{\mathrm{C}}(Q^2) + \frac{1}{3}(\frac{1}{2} + (1+\eta)\tan^2(\theta/2))G_{\mathrm{M}}^2(Q^2)}{A(Q^2) + B(Q^2)\tan^2(\theta/2)}\,. \end{aligned} \tag{5.72}$$

Comparison with Covariant Light-Front Dynamics

The covariant structure of the bound-state current $J^\mu_{\mathrm{V}}(\boldsymbol{k}'_{\mathrm{C}}, \mu'_j, \boldsymbol{k}_{\mathrm{C}}, \mu_j, K_{\mathrm{e}})$ resembles the corresponding one obtained within the covariant light-front approach of Refs. [KS94, CDKM98]. In these works the authors encounter 8 spurious contributions to the current that are associated with ω^μ. These ω-dependent spurious contributions correspond to our K_{e}-dependent spurious contributions. As in the pseudoscalar case, our spurious contributions to the spin-1 current can be traced back to the violation of cluster separability (cf. Sec 3.4.4). The ω-dependent contributions of Ref. [CDKM98] are rather the consequence of the most general ansatz for a current of a vector bound state. The difference to the pseudoscalar case is, however, that we cannot completely get rid of all 8 spurious contributions by simply taking the $k \to \infty$ limit. This resembles the situation in standard light-front dynamics with $\omega = (1, 0, 0, -1)$, in which the extraction of the form factors is based on the plus component of the current operator. By restricting to the plus component in the standard approach the 4 spurious contributions of $B_1, \ldots, B_4$, proportional to ω^μ, are eliminated. However, the contributions of $B_5, \ldots, B_8$ survive which lead to the violation of the angular condition. In this sense the prescription of taking the limit $k \to \infty$ in our approach can be compared to taking the plus component of the current operator in standard light-front dynamics.

The only consistent way to extract the physical form factors unambiguously in covariant light front dynamics is the method of projecting them out of the current tensor by means of appropriate tensors (cf. Refs. [KS94, CDKM98] and the above discussion). After elimination of the spurious contributions the spin matrix elements of the plus component of the remaining physical part satisfy the usual angular condition, Eq. (5.62).

Comparison with Point-Form Spectator Approximation

The point-form of relativistic dynamics has also been used to calculate the elastic form factors of a vector system, cf. e.g. Ref. [AKP01]. Similar as in the point-form spectator model the Bakamjian-Thomas type framework is only applied on the Hilbert space of the 2 constituents (and not on the electron-bound-state Hilbert space as in our case). This means that cluster separability is trivially satisfied. The point-form Bakamjian-Thomas construction is used to obtain the bound-state wave function and the bound-state mass which are then inserted into a general ansatz for a Lorentz covariant electromagnetic bound-state current for a spin-1 system. The independent matrix elements of this spectator current are defined in the Breit frame where the $J^{\mu}_{\mathrm{V}}(1,-1)$ contribution vanishes. The constraints from current conservation are also imposed in the Breit frame where they are most easily satisfied. Due to the kinematic nature of Lorentz transformations in the point form the current can be transformed into any arbitrary frame. This procedure ensures that the angular condition is satisfied. The 3 electromagnetic form factors are then extracted in the Breit frame from the 3 independent current matrix elements. As in the case of the spectator model, the momentum transfer on the active constituent is greater than the momentum transfer on the bound state [AKP01].

Chapter 6

Models

6.1 Introduction

In order to carry out a numerical analysis of the form factors derived in the previous chapter we have to specify the dynamics to obtain a bound-state wave function and a bound-state mass that can be inserted into the analytical expressions for the form factors. In this chapter we introduce the particular models we will be using in order to describe the interaction between the constituents. For simplicity we will restrict ourselves to instantaneous interactions which can be used within the Bakamjian-Thomas framework without losing Poincaré invariance. According to Eq. (3.8) the term $\hat{m}_{\mathrm{int}}$ describing this instantaneous interaction is added to the free invariant two-particle mass operator $\hat{m}_{12}$. For hadrons, such as the π meson (pion) or the ρ meson, we need a confining quark-antiquark interaction which will be modeled in our case by a simple harmonic-oscillator potential [KP91]. For nuclei, such as the deuteron, the interaction between the 2 nucleons is described by a simple Walecka-type two-meson-exchange model. In the static approximation each term of this potential becomes a usual (instantaneous) Yukawa interaction.

6.2 Harmonic-Oscillator Model for Mesons

6.2.1 Wave Function

The fact that particles with color, like quarks, are not observed as free particles is known as *confinement*. The three-dimensional isotropic harmonic oscillator provides already a simple analytically solvable model for 2 quarks with a confining interaction. In the following we will restrict ourselves to the case of equal quark masses m_{q}. We start our rather brief discussion, which goes along the lines of Refs. [KP91,Kra01], by squaring the mass operator in Eq. (3.8) to obtain

$$\hat{m}_{\mathrm{C}}^2 = \hat{m}_{12}^2 + \hat{\hat{m}}_{\mathrm{int}}^2 \, . \tag{6.1}$$

By setting

$$\hat{\hat{m}}_{\mathrm{int}}^2 = -4a^2 \boldsymbol{\nabla}_{\tilde{\boldsymbol{k}}}^2 \, , \tag{6.2}$$

the square of the total mass operator $\hat{m}_{\mathrm{C}}^2$ in Eq. (6.1) takes the form of a harmonic-oscillator Hamiltonian. Here the parameter a is the oscillator length. The corresponding eigenvalue problem for $\hat{m}_{\mathrm{C}}^2$

$$\hat{m}_{\mathrm{C}}^2 \Psi(\tilde{\boldsymbol{k}}) = m_{\mathrm{C}}^2 \Psi(\tilde{\boldsymbol{k}}) \tag{6.3}$$

leads to the eigenfunctions $\Psi(\tilde{\boldsymbol{k}}) = \Psi_{nl\mu_l}(\tilde{\boldsymbol{k}}) = u_{nl}(\tilde{k}) Y_{l\mu_l}(\hat{\tilde{\boldsymbol{k}}})$. Here the radial wave function is given by

$$u_{nl}(\tilde{k}) = \frac{1}{\pi^{\frac{1}{4}} a^{\frac{3}{2}}} \sqrt{\frac{2^{n+l+2} n!}{(2n+2l+1)!!}} L_n^{l+\frac{1}{2}} \left(\frac{\tilde{k}^2}{a^2}\right) \left(\frac{\tilde{k}}{a}\right)^l \mathrm{e}^{-\frac{\tilde{k}^2}{2a^2}} \tag{6.4}$$

where $L_n^{l+\frac{1}{2}}$ are the generalized Laguerre polynomials. The eigenvalues of $\hat{m}_{\mathrm{C}}^2$ are given by

$$m_{nl}^2 = 8a^2 \left(2n + l + \frac{3}{2}\right) + 4m_{\mathrm{q}}. \tag{6.5}$$

6.2.2 Parameters

There are just 2 free parameters in this simple model, the oscillator parameter a and the quark mass m_{q}. For the simplest case of the ground state the wave function reads

$$u_{00}(\tilde{k}) = \frac{2}{\pi^{\frac{1}{4}} a^{\frac{3}{2}}} \mathrm{e}^{-\frac{\tilde{k}^2}{2a^2}} . \tag{6.6}$$

The wave function is solely determined by the oscillator parameter a (cf. Eq. (6.4)). We are going to use 2 sets of parameters which are fixed either by fitting the electromagnetic pion form factor or by fitting the mass spectra. For the latter we observe that a free constant c_0 can be added to the confinement potential to shift the mass spectrum without changing the wave function. We have fixed the parameters a, m_{q} and c_0 for the harmonic-oscillator confinement potential through the vector-meson spectrum as done in Refs. [Kra01, KSK03]. With the values for the parameters $a = 312$ MeV, $c_0 = -1.04$ GeV^2 and $m_{\mathrm{q}} = 340$ MeV, the masses m_{00} and m_{10} of the vector-meson ground states and first excited states, respectively, are reasonably well reproduced [KSK03]. Applying them to the π and ρ meson and its excitations we observe that the first and second radial excitations are about 10% too high as compared to experiment and the π and ρ ground state have a mass of 770 MeV [Kra01, KSK03]. These are quite reasonable values for a pure central confining potential in view of the fact that spin-spin forces from an additional hyperfine interaction can bring them close to the experimental masses [CKP83].

6.3 Walecka-Type Model for the Deuteron

In this section we propose a simple nucleon-nucleon interaction potential that is inspired by the, so-called, *Walecka model* [Wal74]. The derivation presented here can also be found in Ref. [BB10]. It is the first step of a benchmark calculation with the purpose to reach unanimity in different approaches of few-body physics regarding the definition of 'relativistic effects'. The idea is to find a common ground on which the deuteron electromagnetic form factors are calculated in various approaches and then compared with each other. All numerical computations of this section have been carried out with MATHEMATICA©.

6.3.1 Introduction

We define an interaction Lagrangean density that is simple enough to derive a simple, effective nucleon-nucleon interaction, but realistic enough in the sense that this interaction supports an s-wave bound state that resembles the s-wave part of the deuteron. The Lagrangean chosen is inspired by the $\sigma-\omega$-model, also known as the Walecka model [Wal74], which is also often referred to as *quantum hadrodynamics* [SW97]. The present model means a drastic simplification, which, of course, does not meet the sophistication of realistic nucleon-nucleon interactions found to be needed to achieve precise agreement with the data. Below we apply this idea in the simplest possible context, namely to write the interaction in the form of a static potential to be used in the non-relativistic Schrödinger equation. Our model is compared throughout to the Malfliet-Tjon potential [MT69]. The Walecka model requires a regularization procedure for which we take Pauli-Villars regularization [PV49]. This amounts to introducing for every exchanged physical boson an unphysical one that regulates the boson propagator in such a way that the interaction defined by boson exchange becomes well-behaved in momentum space.

6.3.2 Lagrangean Density of the Walecka Model

We use the system of natural units $\mathrm{c} = \hbar = 1$, which means that masses and momenta are given in MeV and radii in 1/MeV. The translation to lengths in fm is given by $\hbar\,\mathrm{c} = 197.3$ MeV fm.

The interaction Lagrangean densities in the Walecka model are given by [Wal74, Nag75, Rij74]

$$\hat{\mathcal{L}}^{\mathrm{N}\sigma}_{\mathrm{int}}(x) = g_\sigma \hat{\bar{\psi}}_{\mathrm{N}}(x)\hat{\psi}_{\mathrm{N}}(x)\hat{\sigma}(x) \tag{6.7}$$

and

$$\hat{\mathcal{L}}^{\mathrm{N}\omega}_{\mathrm{int}}(x) = \mathrm{i}\, g_\omega \hat{\bar{\psi}}_{\mathrm{N}}(x)\gamma_\mu\hat{\psi}_{\mathrm{N}}(x)\hat{\omega}^\mu(x) + \frac{f_\omega}{4m_{\mathrm{N}}}\hat{\bar{\psi}}_{\mathrm{N}}(x)\sigma_{\mu\nu}\hat{\psi}_{\mathrm{N}}(x)(\partial^\mu\hat{\omega}^\nu(x) - \partial^\nu\hat{\omega}^\mu(x)). \tag{6.8}$$

Here $\psi_{\mathrm{N}}(x)$ denotes the nucleon field of mass m_{N}, $\sigma(x)$ denotes a neutral scalar meson field of mass m_σ and $\omega^\mu(x)$ denotes a neutral vector meson field of mass m_ω. $\hat{\mathcal{L}}^{\mathrm{N}\sigma}_{\mathrm{int}}(x)$ describes the coupling of the scalar meson (σ) to the nucleons and $\hat{\mathcal{L}}^{\mathrm{N}\omega}_{\mathrm{int}}(x)$ describes the coupling of the vector meson (ω) to the nucleons. Using the Feynman rules the second-order amplitudes for scalar and vector exchange become, respectively

$$\begin{aligned}
m^{\mathrm{N}\sigma}_{\mathrm{int}}(\tilde{k}_1', \tilde{k}_1) &= g_\sigma^2 \bar{\tilde{u}}_{\tilde{\mu}_1'}(\tilde{\boldsymbol{k}}_1')\tilde{u}_{\tilde{\mu}_1}(\tilde{\boldsymbol{k}}_1)\frac{1}{(\tilde{k}_1' - \tilde{k}_1)^2 - m_\sigma^2}\bar{\tilde{u}}_{\tilde{\mu}_2'}(\tilde{\boldsymbol{k}}_2')\tilde{u}_{\tilde{\mu}_2}(\tilde{\boldsymbol{k}}_2)\,, \quad (6.9)\\
m^{\mathrm{N}\omega}_{\mathrm{int}}(\tilde{k}_1', \tilde{k}_1) &= -g_\omega^2 \bar{\tilde{u}}_{\tilde{\mu}_1'}(\tilde{\boldsymbol{k}}_1')\gamma_\mu\tilde{u}_{\tilde{\mu}_1}(\tilde{\boldsymbol{k}}_1)\frac{\mathrm{g}^{\mu\nu} + (\tilde{k}_1'^\mu - \tilde{k}_1^\mu)(\tilde{k}_2'^\nu - \tilde{k}_2^\nu)/m_\omega^2}{(\tilde{k}_1' - \tilde{k}_1)^2 - m_\omega^2}\\
&\quad \times\bar{\tilde{u}}_{\tilde{\mu}_2'}(\tilde{\boldsymbol{k}}_2')\gamma_\nu\tilde{u}_{\tilde{\mu}_2}(\tilde{\boldsymbol{k}}_2)\,. \quad (6.10)
\end{aligned}$$

Here we use Dirac spinors normalized to unity, i.e. $\tilde{u}_\sigma(\boldsymbol{p}) := \frac{1}{\sqrt{2m}} u_\sigma(\boldsymbol{p})$. Note that for simplicity we take only pure vector exchange for the ω meson. This can be justified by looking at a comparison of different models for the vector-meson exchange in Ref. [Erk74]. Realistic models favour no, or only very small tensor coupling for the ω meson.

For the Pauli-Villars particles, the same basic forms for the second-order matrix elements are used with one difference: the amplitudes have opposite sign. This sign difference is, of course, the reason why the Pauli-Villars bosons provide regularization of the potentials.

Static Potentials in Momentum Space

In the static (non-relativistic) approximation the amplitudes turn out to be (for details see App. G)

$$m_{\text{int}}^{\text{N}\sigma}(\tilde{\boldsymbol{q}}_1) = -\frac{g_\sigma^2}{\tilde{\boldsymbol{q}}_1^2 + m_\sigma^2} \tag{6.11}$$

and

$$m_{\text{int}}^{\text{N}\omega}(\tilde{\boldsymbol{q}}_1) = \frac{g_\omega^2}{\tilde{\boldsymbol{q}}_1^2 + m_\omega^2}\,, \tag{6.12}$$

where $\tilde{\boldsymbol{q}}_1 := \tilde{\boldsymbol{k}}_1' - \tilde{\boldsymbol{k}}_1$ denotes the exchanged three-momentum. The energies occurring in the Dirac spinors have been approximated by the nucleon masses and only the large components of the Dirac spinors are retained.

Potentials in Coordinate Space

The potentials in configuration space are given by the Fourier transforms of expressions (6.11) and (6.12):

$$V^{\text{N}\sigma}(\boldsymbol{r}) = \int \frac{\mathrm{d}^3\tilde{q}_1}{(2\pi)^3}\, m_{\text{int}}^{\text{N}\sigma}(\tilde{\boldsymbol{q}}_1)\, \mathrm{e}^{\mathrm{i}\tilde{\boldsymbol{q}}_1\cdot\boldsymbol{r}}\,. \tag{6.13}$$

This integral can be done by contour integration giving the usual Yukawa potential [PS95]

$$V^{\text{N}\sigma}(r) = -\frac{g_\sigma^2}{4\pi}\frac{\mathrm{e}^{-m_\sigma r}}{r}\,, \tag{6.14}$$

where $r = |\boldsymbol{r}|$. Similarly for the vector-meson-exchange potential:

$$V^{\text{N}\omega}(r) = \frac{g_\omega^2}{4\pi}\frac{\mathrm{e}^{-m_\omega r}}{r}\,. \tag{6.15}$$

Pauli-Villars Regularization

In the Pauli-Villars regularization prescription one introduces fictitious heavy particles in the Lagrangean density. Then the regularized interaction Lagrangean density is given by[1]

$$\begin{aligned}\hat{\mathcal{L}}_{\text{int}}(x) \;=\;& g_\sigma \hat{\bar{\psi}}_{\text{N}}(x)\hat{\psi}_{\text{N}}(x)\hat{\sigma}(x) + \mathrm{i}\, g_\omega \hat{\bar{\psi}}_{\text{N}}(x)\gamma_\mu\hat{\psi}_{\text{N}}(x)\hat{\omega}^\mu(x)\\ &+\mathrm{i}\, g_\sigma \hat{\bar{\psi}}_{\text{N}}(x)\hat{\psi}_{\text{N}}(x)\hat{\sigma}_{\text{PV}}(x) + g_\omega \hat{\bar{\psi}}_{\text{N}}(x)\gamma_\mu\hat{\psi}_{\text{N}}(x)\hat{\omega}^\mu_{\text{PV}}(x)\,,\end{aligned} \tag{6.16}$$

---

[1] Note that we include only one Pauli-Villars field for either meson. This is sufficient for cutting off the kernels in momentum space if the effective interaction is obtained by taking matrix elements between on-mass-shell nucleons. Otherwise, e.g. if one uses the Bethe-Salpeter equation, more Pauli-Villars fields are needed [Kar].

where $\sigma_{\mathrm{PV}}(x)$ and $\omega^{\mu}_{\mathrm{PV}}(x)$ are the Pauli-Villars fields with large masses Λ_σ and Λ_ω, respectively. Note that we couple the Pauli-Villars bosons with the same strength as the physical bosons but with an additional factor i, which translates in second order into a relative minus sign of the amplitudes.

This introduction of Pauli-Villars fields in the Lagrangean results in making the following replacement for the σ-meson propagators in Eq. (6.11):

$$\frac{1}{\tilde{\boldsymbol{q}}_1^2+m_\sigma^2} \longrightarrow \frac{1}{\tilde{\boldsymbol{q}}_1^2+m_\sigma^2}-\frac{1}{\tilde{\boldsymbol{q}}_1^2+\Lambda_\sigma^2}\,. \tag{6.17}$$

Similarly for the ω-meson propagator in Eq. (6.12):

$$\frac{1}{\tilde{\boldsymbol{q}}_1^2+m_\omega^2} \longrightarrow \frac{1}{\tilde{\boldsymbol{q}}_1^2+m_\omega^2}-\frac{1}{\tilde{\boldsymbol{q}}_1^2+\Lambda_\omega^2}\,. \tag{6.18}$$

Therefore, the Walecka potential in configuration space finally reads

$$V(r)=-\frac{g_\sigma^2}{4\pi}\frac{\mathrm{e}^{-m_\sigma r}}{r}+\frac{g_\sigma^2}{4\pi}\frac{\mathrm{e}^{-\Lambda_\sigma r}}{r}+\frac{g_\omega^2}{4\pi}\frac{\mathrm{e}^{-m_\omega r}}{r}-\frac{g_\omega^2}{4\pi}\frac{\mathrm{e}^{-\Lambda_\omega r}}{r}\,. \tag{6.19}$$

6.3.3 Coordinate Space

Solving the Schrödinger Equation and Fixing the Parameters

The two-body s-wave ($l = 0$) Schrödinger equation for the reduced deuteron wave function $w_0(r) := r\,\tilde{u}_0(r)$ reads

$$\left[-\frac{\hbar^2}{2m_{\mathrm{red}}}\frac{\mathrm{d}^2}{\mathrm{d}r^2}+V(r)\right]w_0(r)=E_{\mathrm{B}}\,w_0(r)\,, \tag{6.20}$$

where

$$2m_{\mathrm{red}}=\frac{2m_{\mathrm{p}}m_{\mathrm{n}}}{m_{\mathrm{p}}+m_{\mathrm{n}}}=938.92\ \mathrm{MeV/c^2}\approx m_{\mathrm{N}}\,. \tag{6.21}$$

The potential has the form, (re)expressing r in fm and the λ's in fm^{-1}

$$V(r)=\hbar\,\mathrm{c}\left[-\frac{g_\sigma^2}{4\pi}\frac{\mathrm{e}^{-r/\lambda_\sigma}}{r}+\frac{g_\sigma^2}{4\pi}\frac{\mathrm{e}^{-r/\lambda_{\mathrm{PV}\sigma}}}{r}+\frac{g_\omega^2}{4\pi}\frac{\mathrm{e}^{-r/\lambda_\omega}}{r}-\frac{g_\omega^2}{4\pi}\frac{\mathrm{e}^{-r/\lambda_{\mathrm{PV}\omega}}}{r}\right]\,, \tag{6.22}$$

where the quantities λ are the Compton wavelengths of the corresponding meson masses, e.g. $\lambda_\sigma = \hbar/m_\sigma\mathrm{c}$.

We use the existing data on the recommended σ-meson mass, the experimental ω-meson mass, the deuteron binding energy, and the triplet scattering length to fix the parameters. For the Pauli-Villars particles we use the mass values (cut off values) $\Lambda_\sigma = 1000$ MeV and $\Lambda_\omega = 1500$ MeV, which are reasonable values for these cut offs, although they are somewhat smaller than usual. We did not vary them, because the model proposed here is simply not realistic enough to warrant much effort in this direction. Yet, we wanted this model to produce a reasonable s-wave deuteron wave function. The values of the parameters we found are given in Tab. 6.1.

The potential is depicted in Fig. 6.1 together with the simple Malfliet-Tjon-III potential [MT69]. It is clear that the present model has stronger attraction at intermediate range and stronger repulsion at short range than the Malfliet-Tjon potential. This difference can be expected to show up in the bound-state wave function at intermediate range.

parameters (units)	present	present, no PV	MT [MT69]
E_{B} (MeV)	-2.224575	-3.36772	-2.27203
a_{t} (fm)	5.4151	4.58658	5.4739
$g_\sigma^2/4\pi$	6.31	6.31	3.22749
$g_\omega^2/4\pi$	18.617	18.617	7.40758
λ_σ (fm) (m_σ (MeV/c^2))	0.493317 (400)	0.493317 (400)	0.643087 (306.8)
λ_ω (fm) (m_ω (MeV/c^2))	0.25211 (782.7)	0.25211 (782.7)	0.321543 (613.6)
$\lambda_{\mathrm{PV}\sigma}$ (fm) (Λ_σ (MeV/c^2))	0.19732 (1000)	0 (∞)	0 (∞)
$\lambda_{\mathrm{PV}\omega}$ (fm) (Λ_ω (MeV/c^2))	0.131551 (1500)	0 (∞)	0 (∞)

Table 6.1: The values for the masses and coupling constants are chosen such that the deuteron binding energy E_{B} and the scattering length a_t are well reproduced. These values are also similar to those proposed in [Erk74].

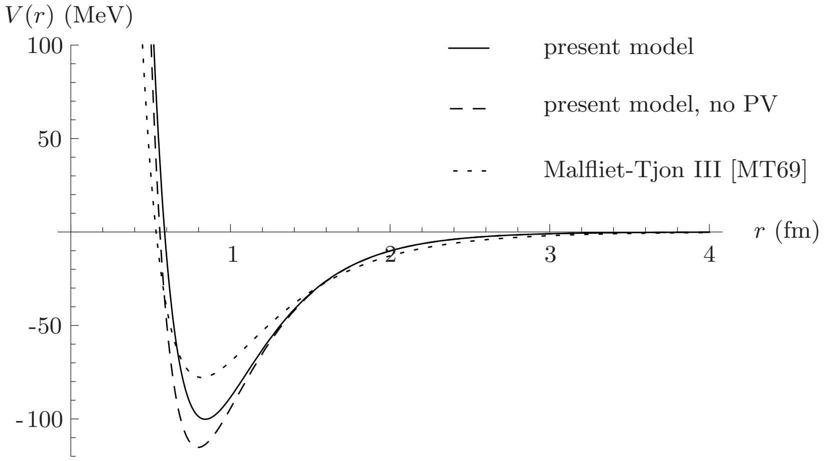

Figure 6.1: The present potential with and without Pauli-Villars regularization compared with the Malfliet-Tjon potential [MT69]. The parameters are given in Tab. 6.1.

The Schrödinger equation (6.20) is solved numerically, with the solution $w_0(r)$ being subject to the boundary condition $w_0(0) = 0$. The normalized bound state wave function $w_0(r)$ is depicted in Fig. 6.2.

As a characteristic quantity that measures the quality of the wave function non-locally, we calculated the mean-square radius defined by [BLOT90]

$$\langle r^2 \rangle := \frac{1}{4} \int_0^\infty \mathrm{d}r\, r^2 w_0^2(r)\,. \tag{6.23}$$

We find a value for the root-mean-squared radius $\sqrt{\langle r^2 \rangle} = 1.95015$ fm close to Malfliet-Tjon's value $\sqrt{\langle r^2 \rangle} = 1.97625$ fm. This is also in accordance with other results for the deuteron root-mean-square radius [BLOT90]. The triplet scattering length a_{t} is obtained from the solution $w_0(r)$ of the Schrödinger equa-

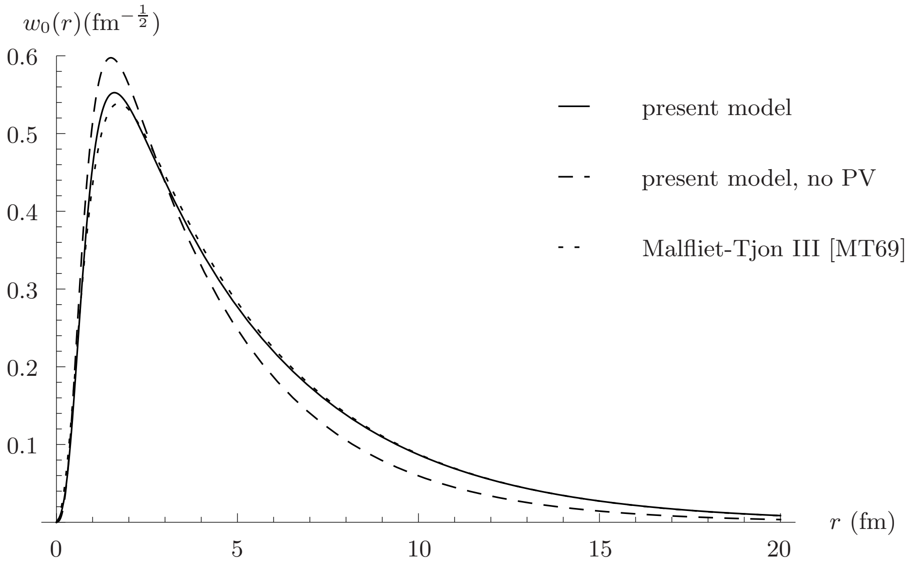

Figure 6.2: Present model wave functions with and without Pauli-Villars regularization compared with the Malfliet-Tjon model wave function in units of $\mathrm{fm}^{-\frac{1}{2}}$. The Schrödinger equation for the Malfliet-Tjon potential is solved with the parameters given in Tab. 6.1.

tion Eq. (6.20) corresponding to $E_\mathrm{B} = 0$, see Fig. 6.3. We find the value $a_\mathrm{t} = 5.421$ fm, compared to the experimental value of 5.432 fm [Rij06]. It is amusing to check the importance of the Pauli-Villars bosons in the static approximation, where they are not needed for convergence. In Table 6.1 we give the values of the energy and the scattering length in the situation that these bosons are omitted. Clearly, the values of the bound-state energy, -3.368 MeV, compared to -2.225 MeV, and 4.587 fm compared to 5.421 fm, are quite reasonable, although of course far outside the error bounds of the experimental data.

Body Form Factor

As we do not specify the charges of the fermions in the simple benchmark model, we calculate the body form factor of the bound state only. For the s-wave bound state found here, it is given by the well-known formula[2] [BJ76]

$$F_\mathrm{B}(\tilde{q}_1) = \int_0^\infty \mathrm{d}r\, j_0(\tilde{q}_1 r)\, w_0^2(r)\,, \tag{6.24}$$

where $j_0(\tilde{q}_1 r) = \sin(\tilde{q}_1 r)/(\tilde{q}_1 r)$ is the first spherical Bessel function and $w_0(r)$ is normalized as

$$\int_0^\infty \mathrm{d}r\, w_0^2(r) = 1\,. \tag{6.25}$$

---

[2] $F_\mathrm{B}(\tilde{q}_1)$ corresponds to the electric charge form factor $G_\mathrm{C}(2\tilde{q}_1)$ (cf. Eq. 5.65) for point-like nucleons and for the relativistic kinematical factors and spin-rotation factors set equal to one.

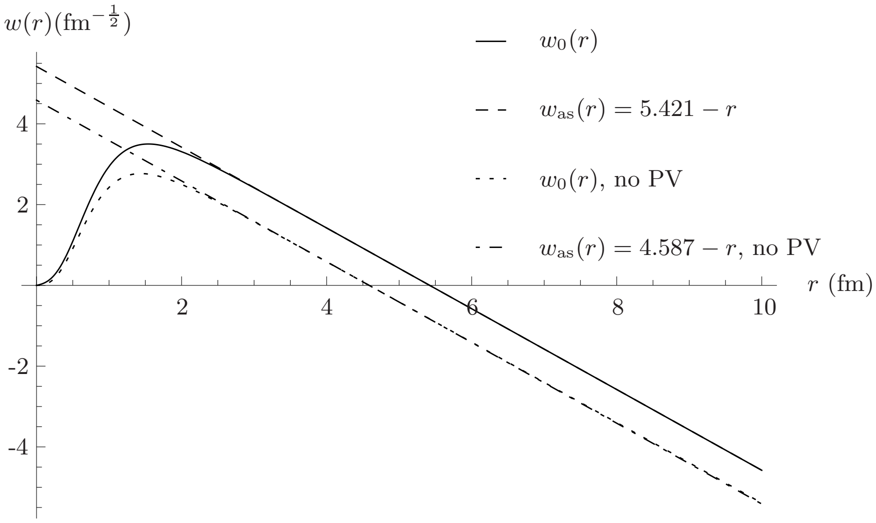

Figure 6.3: Wave functions at energy $E_{\mathrm{B}} = 0$ for the present model with and without Pauli-Villars regularization included in the potential. The scattering length is determined by a linear fit to the wave function at large r.

This normalization guarantees $F_{\mathrm{B}}(0) = 1$. The resulting form factor for the present model is depicted in Fig. 6.4.

The small-$\tilde{q}_1$ behaviour can be read off in the usual way from the small-x behaviour of the spherical Bessel function, namely $j_0(x) \sim 1 - x^2/6$, which gives

$$F_{\mathrm{B}}(\tilde{q}_1) \sim 1 - \frac{\tilde{q}_1^2}{6} \int_0^\infty \mathrm{d}r \, r^2 \, w_0^2(r) \,. \tag{6.26}$$

In Fig. 6.5 we show the form factor at small $\tilde{q}_1$ together with the limiting form given in Eq. (6.26). (Note the factor 4 that comes from the factor 1/4 in the definition of $\langle r^2 \rangle$, Eq. (6.23).)

6.3.4 Momentum Space

Solving the Integral Equation

In order to facilitate the comparison of our model with calculations restricted to momentum space, we transformed the Schrödinger equation to momentum space which is the integral equation obtained by Fourier transforming Eq. (6.20):

$$\frac{\tilde{k}^2}{m_{\mathrm{N}}} u_0(\tilde{k}) + \int \frac{\mathrm{d}^3\tilde{k}'}{(2\pi)^3} m_{\mathrm{int}}(|\tilde{\boldsymbol{k}}_1 - \tilde{\boldsymbol{k}}_1'|) \, u_0(\tilde{k}') = E_{\mathrm{B}} \, u_0(\tilde{k}) \,, \tag{6.27}$$

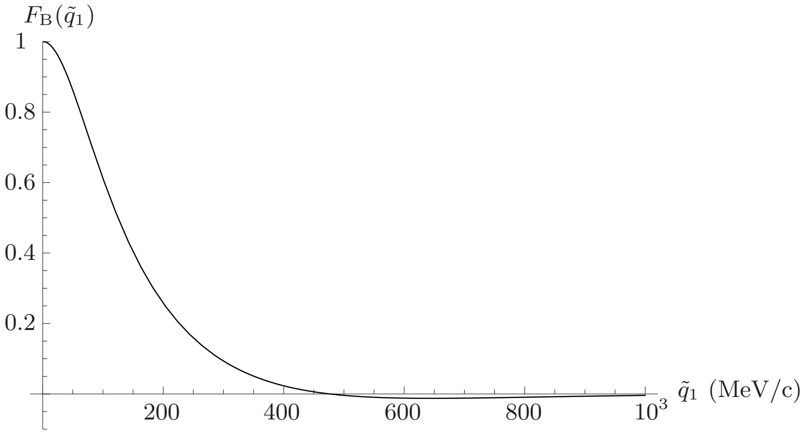

Figure 6.4: The form factor in the present model including Pauli-Villars regularization. The form factor for the Malfliet-Tjon deuteron is indistinguishable on this scale.

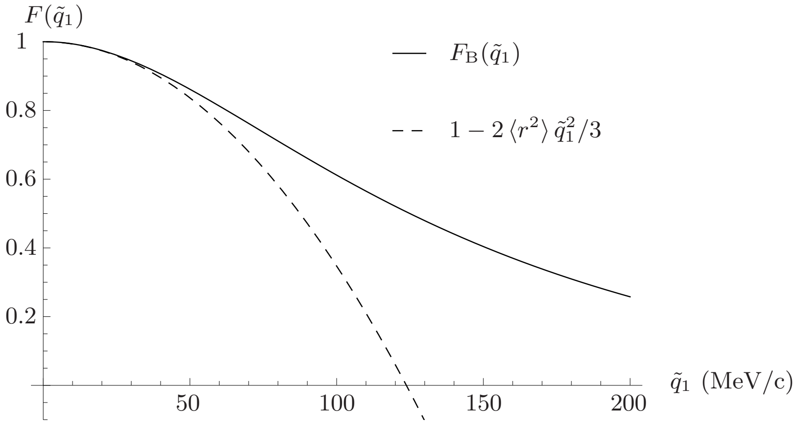

Figure 6.5: The form factor together with the form for small $\tilde{q}_1$.

where

$$\begin{aligned} m_{\rm int}(|\tilde{\boldsymbol{k}} - \tilde{\boldsymbol{k}}'|) &= -\frac{g_\sigma^2}{(\tilde{\boldsymbol{k}} - \tilde{\boldsymbol{k}}')^2 + m_\sigma^2} + \frac{g_\sigma^2}{(\tilde{\boldsymbol{k}} - \tilde{\boldsymbol{k}}')^2 + \Lambda_\sigma^2} \\ &\quad + \frac{g_\omega^2}{(\tilde{\boldsymbol{k}} - \tilde{\boldsymbol{k}}')^2 + m_\omega^2} - \frac{g_\omega^2}{(\tilde{\boldsymbol{k}} - \tilde{\boldsymbol{k}}')^2 + \Lambda_\omega^2}\,. \end{aligned} \tag{6.28}$$

Note that Eq. (6.25) fixes the normalization of $u_0(\tilde{k})$ as

$$\int_0^\infty {\rm d}\tilde{k}\, \tilde{k}^2\, u_0^2(\tilde{k}) = (2\pi)^3\,. \tag{6.29}$$

This defines the difference between $u_0(\tilde{k})$ and $u_{00}(\tilde{k})$ from Eq. (3.28) by a factor of $(2\pi)^{\frac{3}{2}}$:

$$u_{00}(\tilde{k}) \equiv \frac{1}{(2\pi)^{\frac{3}{2}}} u_0(\tilde{k}) \,. \tag{6.30}$$

Since there is only one bound-state for the deuteron, we have left away the index $n = 0$ which also served as a distinction between $u_0(\tilde{k})$ and $u_{00}(\tilde{k})$.[3] The angular integrations can be done by expanding $m_{\text{int}}(|\tilde{\boldsymbol{k}}_1 - \tilde{\boldsymbol{k}}_1'|)$ in terms of partial waves (for a detailed discussion see, e.g. Ref. [vIvdBB00]). The result is

$$\frac{\tilde{k}^2}{m_{\text{N}}} u_0(\tilde{k}) + \frac{1}{8\pi^2} \int_0^\infty \mathrm{d}\tilde{k}' \, m_{\text{int}}(\tilde{k}, \tilde{k}') \, u_0(\tilde{k}') = E_{\text{B}} u_0(\tilde{k}) \,, \tag{6.31}$$

where

$$\begin{aligned} m_{\text{int}}(\tilde{k}, \tilde{k}') \quad = \quad & \frac{\tilde{k}'}{\tilde{k}} \left\{ -g_\sigma^2 \ln \left[\frac{(\tilde{k} + \tilde{k}')^2 + m_\sigma^2}{(\tilde{k} - \tilde{k}')^2 + m_\sigma^2} \right] + g_\sigma^2 \ln \left[\frac{(\tilde{k} + \tilde{k}')^2 + \Lambda_\sigma^2}{(\tilde{k} - \tilde{k}')^2 + \Lambda_\sigma^2} \right] \right. \\ & \left. + g_\omega^2 \ln \left[\frac{(\tilde{k} + \tilde{k}')^2 + m_\omega^2}{(\tilde{k} - \tilde{k}')^2 + m_\omega^2} \right] - g_\omega^2 \ln \left[\frac{(\tilde{k} + \tilde{k}')^2 + \Lambda_\omega^2}{(\tilde{k} - \tilde{k}')^2 + \Lambda_\omega^2} \right] \right\} . \end{aligned} \tag{6.32}$$

The integral equation (6.31) is solved for the wave function of the bound state with the numerical method of standard Gauss quadrature (for details see, e.g. Ref. [vIvdBB00]). The determination of the energy served as a check of our numerical calculations. Indeed, we found the same energy in momentum space and coordinate space. The momentum-space wave function $u_0(\tilde{k})$ is shown in Fig. 6.6. On this scale, we cannot see the difference between the Malfliet-Tjon wave function and the one obtained with the present model. Looking at Fig. 6.2 we see that in coordinate space the two models differ most below a few fm, so we may expect the momentum-space wave functions to be different at momenta around 200 MeV/c, which turns out to be true, as Fig. 6.7 shows.

For small values of the momenta the momentum-space wave function is dominated by the asymptotic behaviour of the coordinate-space wave function, i.e. $\tilde{u}_0(r) \sim \exp(-\alpha r)$ with $\alpha^2 = -E_{\text{B}} m_{\text{N}}$. The corresponding behaviour in momentum space is $u_0(\tilde{k}) \sim 1/(\alpha^2 + \tilde{k}^2)$. The latter is plotted in Fig. 6.8.

Relativistic Kinetic Energy

The simplest modification of the present model replaces the kinetic-energy operator $\tilde{\boldsymbol{k}}^2/m_{\text{N}}$ by the operator $2\sqrt{\tilde{\boldsymbol{k}}^2 + m_{\text{N}}^2} - 2m_{\text{N}}$. Then the bound-state equation Eq. (6.31) becomes a mass eigenvalue equation (cf. Eq. (3.11))

$$2\sqrt{\tilde{\boldsymbol{k}}^2 + m_{\text{N}}^2} u_0(\tilde{k}) + \int \frac{\mathrm{d}^3\tilde{k}'}{(2\pi)^3} m_{\text{int}}(|\tilde{\boldsymbol{k}}_1 - \tilde{\boldsymbol{k}}_1'|) u_0(\tilde{k}') = (\underbrace{E_{\text{B}}^{\text{rel}} + 2m_{\text{N}}}_{=m_{\text{D}}}) u_0(\tilde{k}) \,. \tag{6.33}$$

It is well known that this replacement effectively weakens the kinetic energy and consequently lowers the energy of the bound state(s) if the potential remains

---

[3] Note that we define $\tilde{\Psi}_{00}(\boldsymbol{r}) = Y_{00}(\hat{\boldsymbol{r}}) \tilde{u}_0(r)$ and its Fourier transform as $\Psi_{00}(\tilde{\boldsymbol{k}}) = Y_{00}(\hat{\tilde{\boldsymbol{k}}}) u_0(\tilde{k})$.

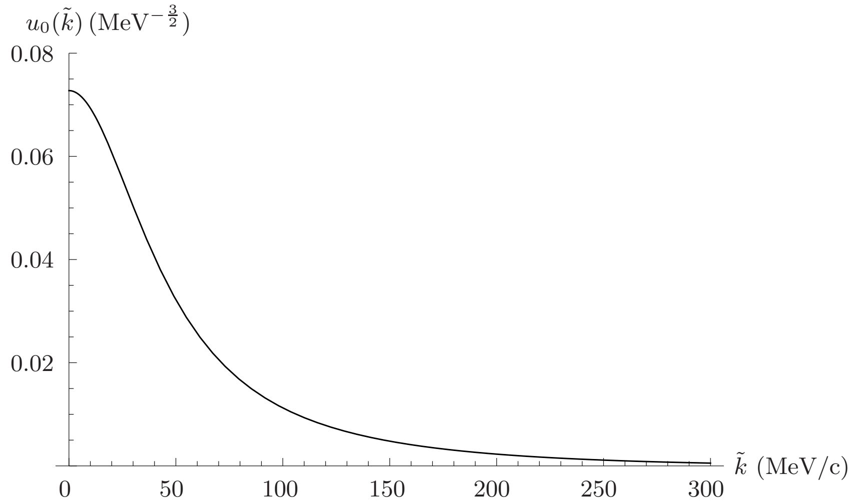

Figure 6.6: The wave function $u_0(\tilde{k})$ in momentum space for the present model including Pauli-Villars regularization. The wave function for the Malfliet-Tjon deuteron is indistinguishable on this scale.

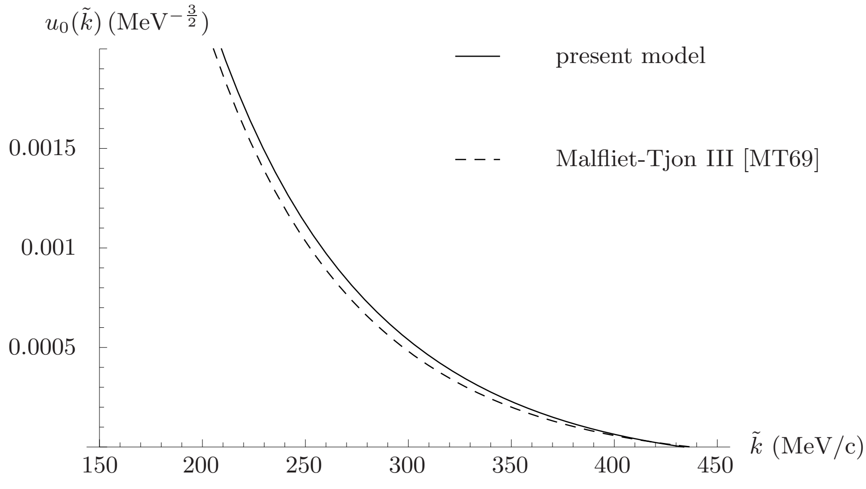

Figure 6.7: The wave function $u_0(\tilde{k})$ in momentum space for the present model including Pauli-Villars regularization and the wave function for the Malfliet-Tjon deuteron for large momenta.

the same. This is indeed what we find. The eigenvalue of the Hamiltonian drops to $E_{\mathrm{B}}^{\mathrm{rel}} = -2.73414$ MeV which gives a deuteron mass of $m_{00} = m_{\mathrm{D}} = 1.87511$ GeV.

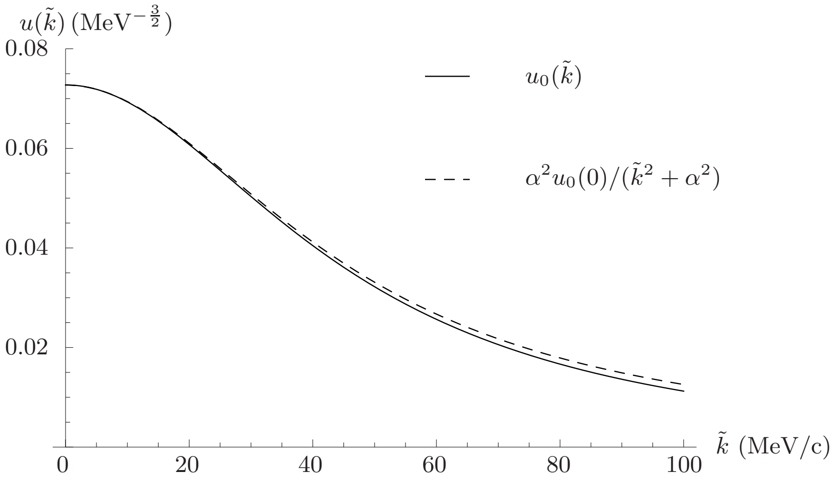

Figure 6.8: The momentum-space wave function $u_0(\tilde{k})$ for the present model including Pauli-Villars regularization and the pole part of this wave function for small momenta.

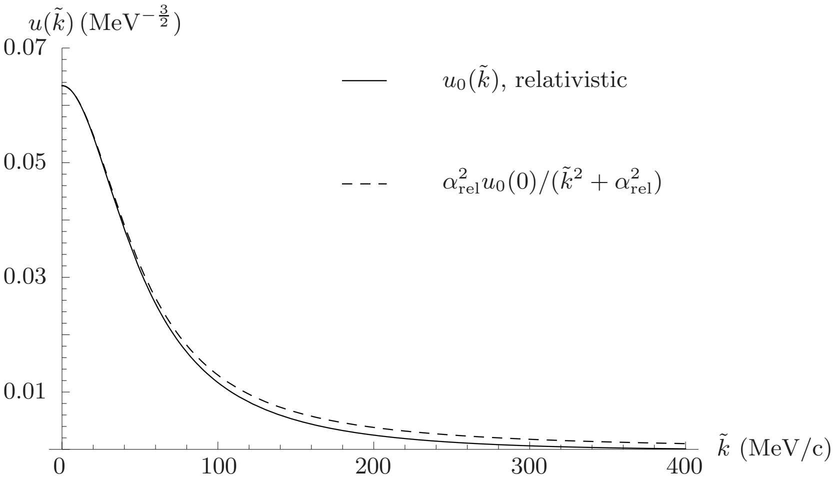

Figure 6.9: The momentum-space wave function $u_0(\tilde{k})$ for the present model including Pauli-Villars regularization and relativistic kinetic-energy operator. Also shown is the pole part.

In Fig. 6.10 we show the momentum-space wave functions for the case where the non-relativistic kinetic-energy operator is used and the one where the relativistic operator is used.

The body form factor expression, Eq. (6.24), is given in momentum space by

$$F_{\mathrm{B}}(\tilde{q}_1)=\frac{1}{4\pi}\int \mathrm{d}^3\tilde{k}\, u_0(\tilde{k})u_0(|\tilde{\boldsymbol{k}}+\tilde{\boldsymbol{q}}_1|)\,. \tag{6.34}$$

In Figs. 6.11 and 6.12 we show again the form factor for the Walecka-type model, but now together with the one where the relativistic kinetic energy is used. The differences between the two are hardly noticeable.

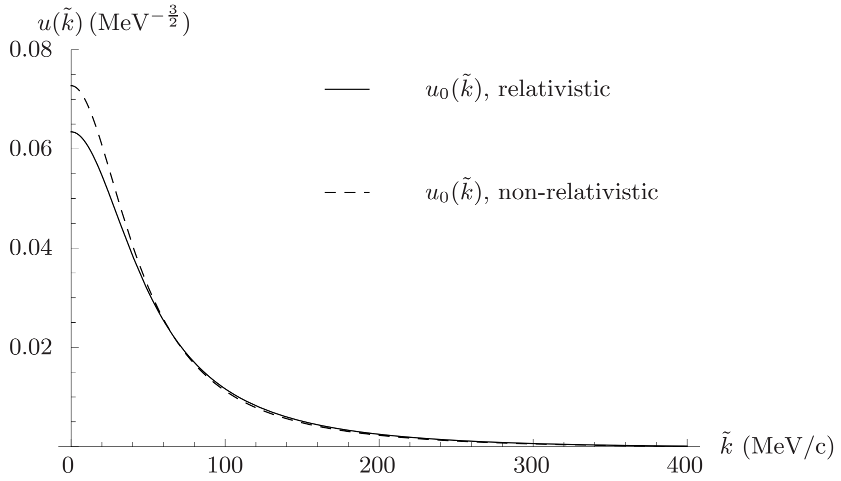

Figure 6.10: The momentum-space wave functions $u_0(\tilde{k})$ for the present model including Pauli-Villars regularization and relativistic and non-relativistic kinetic-energy operator.

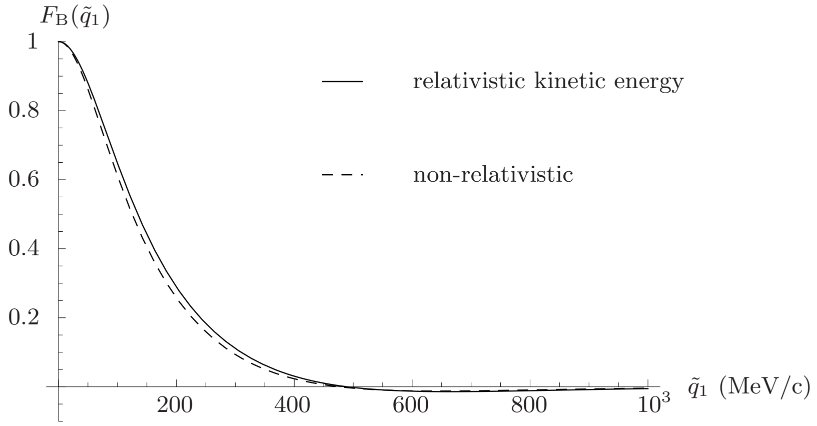

Figure 6.11: A comparison of the form factors obtained for the present model including Pauli-Villars regularization with the relativistic kinetic-energy operator and the non-relativistic one.

Chapter 7

Numerical Results

Having solved the bound-state problem for the harmonic-oscillator potential and the Walecka-type model in the previous chapter we are now ready to make a numerical analysis of the form factor expressions for pseudoscalar and vector bound-states. All computations of this chapter have been done using MATHEMATICA©.

7.1 Electromagnetic π-Meson Form Factor

In the present work confinement between the quark and the antiquark of a charged pion $\pi^{\pm}$ is modeled by the simple harmonic-oscillator potential introduced in Sec. 6.2. There are just 2 free parameters in this simple model, the oscillator parameter a and the constituent-quark mass m_{q}. Using Eq. (5.25) for the form factor a reasonable fit of the experimental data [H$^+$08, B$^+$78, B$^+$76, B$^+$74, B$^+$73, A$^+$86] can be achieved by choosing the parameter values $a = 350$ MeV and $m_{\mathrm{q}} = 210$ MeV, which are taken from Ref. [CCP88]. At this point we shall emphasize that our goal is not to end up with an optimal fit of the pion form factor, but we rather want to exhibit the virtues of our point-form approach and compare it to other attempts to develop microscopic models for hadron form factors.

7.1.1 Numerical Study

We start with a numerical study of the influence of cluster-separability violating effects on the pion current and on the pion form factors. To this end we take the simple harmonic-oscillator wave function, Eq. (6.6), to calculate the pion current, Eq. (4.31).[1] Using our standard kinematics of Eq. (5.11) we find that the current $J^{\mu}_{\pi}(\boldsymbol{k}'_{\mathrm{C}}, k_{\mathrm{C}})$ has actually 2 vanishing components as expected from the theoretical analysis of Sec. 5.2.1: $J^{1}_{\pi}(\boldsymbol{k}'_{\mathrm{C}}, \boldsymbol{k}_{\mathrm{C}}) = J^{2}_{\pi}(\boldsymbol{k}'_{\mathrm{C}}, \boldsymbol{k}_{\mathrm{C}}) = 0$. There are, in general, 2 non-vanishing non-equal components, $J^{0}_{\pi}(\boldsymbol{k}'_{\mathrm{C}}, \boldsymbol{k}_{\mathrm{C}})$ and $J^{3}_{\pi}(\boldsymbol{k}'_{\mathrm{C}}, \boldsymbol{k}_{\mathrm{C}})$, except in the Breit frame ($k = Q/2$) and in the infinite-momentum frame ($k \to \infty$). In the Breit frame the third component is seen to vanish: $J^{3}_{\pi}(\boldsymbol{k}'_{\mathrm{C}}, \boldsymbol{k}_{\mathrm{C}}) = 0$.

---

[1] We have chosen for the 2 parameters, $m_{\mathrm{q}} = 340$ MeV and $a = 312$ MeV. A justification for these values has already been given in Sec. 6.2.2 or can also be found in Ref. [Kra01]. Their precise value, however, is not important for this qualitative study.

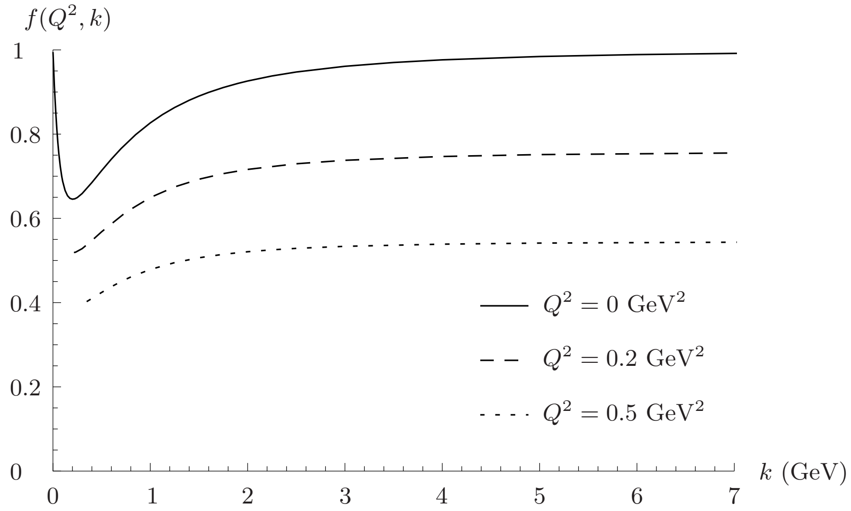

Figure 7.1: Dependence of the physical pion form factor f of Eq. (5.20) on the pion center-of-mass momentum k for different values of the squared momentum transfer Q^2.

This confirms exactly our findings of Sec. 5.2.1, namely that it is not possible to separate the 2 form factors f and $\tilde{b}$ in the Breit frame, which essentially means that one is left with just one form factor (a linear combination of f and $\tilde{b}$).

Nevertheless, for $k > Q/2$ the 2 form factors f and $\tilde{b}$ can be separated uniquely by means of Eq. (5.6). They are then given by Eqs. (5.20) and (5.21) and plotted in Figs. 7.1 and 7.2 versus k for fixed Q^2. One observes that both, the physical form factor f and the spurious form factor $\tilde{b}$ depend on k. The k-dependence of f vanishes rather quickly with increasing k. At the same time the spurious form factor $\tilde{b}$ is seen to vanish for large k. This means by taking the limit $k \to \infty$ effects from the violation of cluster separability are removed. In this limit we also ended up with the simple analytic expression for the form factor F given in Eq. (5.25). This expression has been proved in Sec. 5.3.2 to be equivalent with the standard front-form expression for the pion form factor of Ref. [CCP88] obtained from a spectator current in the $q^+ = 0$ frame.

From Fig. 7.1 we also read off the correct charge of the pion, i.e. $F(0) = \lim_{k\to\infty} f(0,k) = 1$ in units of the elementary charge e. This is only the case for the form factor one gets from the decomposition of the pion current given by Eq. (5.3), which justifies to call f the physical and $\tilde{b}$ the unphysical form factors of the pion [CDKM98]. In addition, we note that the fact that we end up with only one form factor is also confirmed by the observation that $J^0_\pi(\boldsymbol{k}'_\mathrm{C}, \boldsymbol{k}_\mathrm{C}) \to J^3_\pi(\boldsymbol{k}'_\mathrm{C}, \boldsymbol{k}_\mathrm{C})$ in the limit $k \to \infty$.

In Figs. 7.3 and 7.4 we show the Q^2-dependence of the electromagnetic pion form factor $F\left(Q^2\right)$ as evaluated by means of Eq. (5.25) along with experimental data. Also shown is the role of the spin-rotation factor $\mathcal{S}$. The quark spin obviously has a substantial effect on the electromagnetic form factor over nearly the whole momentum-transfer range and thus cannot be neglected [BSFK09].

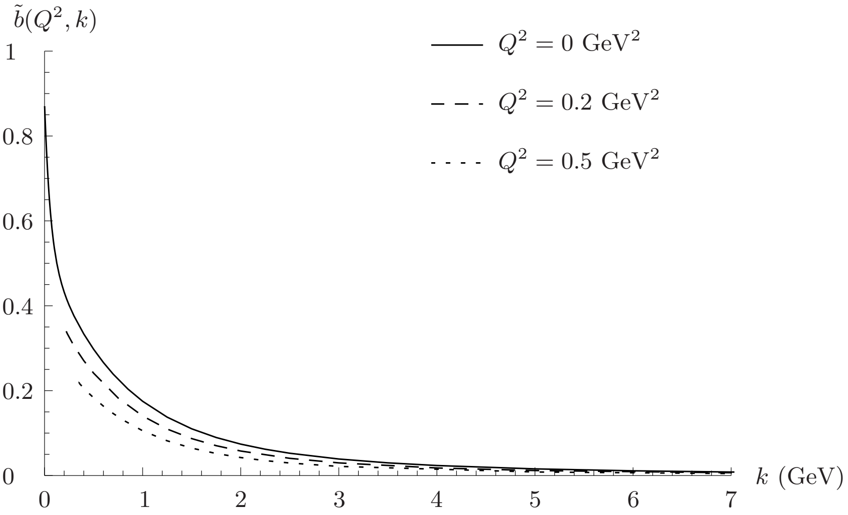

Figure 7.2: Dependence of the spurious pion form factor $\tilde{b}$ of Eq. (5.21) on the pion center-of-mass momentum k for different values of the squared momentum transfer Q^2.

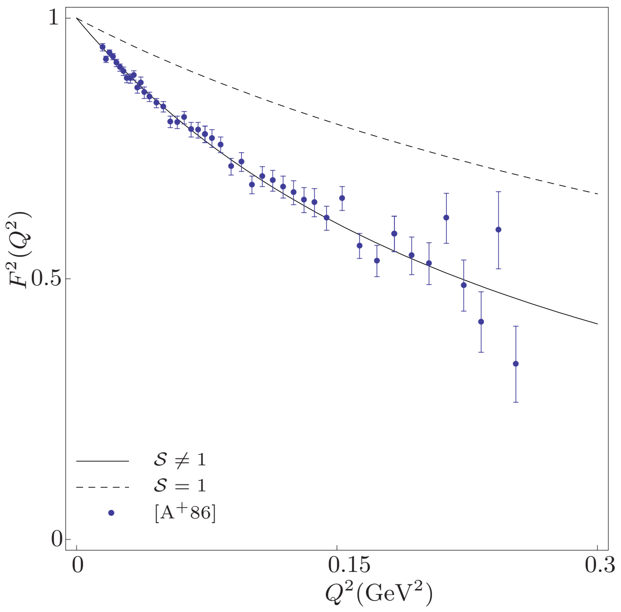

Figure 7.3: Q^2-dependence of the electromagnetic pion form factor squared $F^2\left(Q^2\right)$ in the low-Q^2 region, as evaluated by means of Eq. (5.25) with parameters $a = 350$ MeV and $m_\mathrm{q} = 210$ MeV with and without spin-rotation factor $\mathcal{S}$ [BSFK09]. Data are taken from Ref. [A+86].

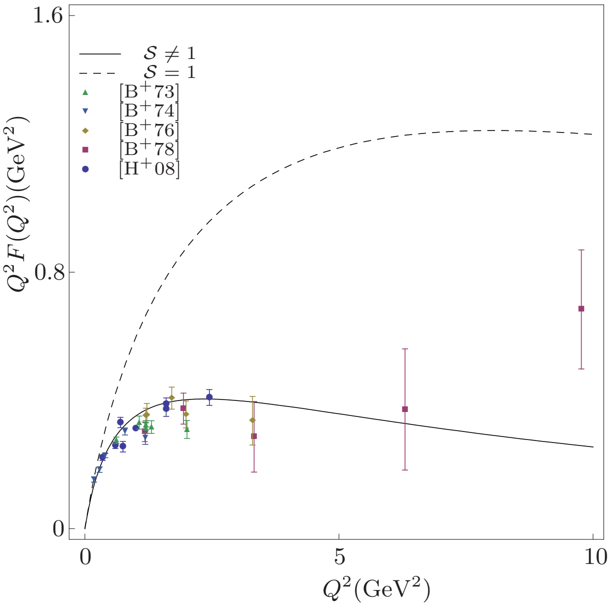

Figure 7.4: Q^2-dependence of the electromagnetic pion form factor scaled by Q^2 as evaluated by means of Eq. (5.25) with the same parameters as in Fig. 7.3 with and without spin-rotation factor $\mathcal{S}$ [BSFK09]. Data are taken from Refs. [B$^+$73, B$^+$76, B$^+$74, B$^+$78, H$^+$08].

7.1.2 Results and Comparisons

We have already mentioned previously that the pion form-factor expression obtained in the point-form spectator model [WBK$^+$01, B$^+$02, MBC$^+$07] is not only determined by the pion wave function, but exhibits also an explicit dependence on the pion mass. Therefore, the spectrum of the mass operator is directly connected with the electromagnetic structure of its eigenstates. This makes it somewhat delicate to compare our form-factor results for the simple harmonic-oscillator confinement potential with corresponding point-form model predictions [BSFK09]. Whereas the wave function is solely determined by the oscillator parameter a (cf. Eq. (6.6)), another free constant c_0 can be added to the confinement potential (cf. Eq. (6.5)) to shift the eigenvalue spectrum. Unlike our results, which do not depend on c_0, the point-form spectator model predictions exhibit a strong dependence on c_0. The parameters $a = 350$ MeV and $m_\mathrm{q} = 210$ MeV as proposed in Ref. [CCP88] give a reasonable fit of our pion form factor with the data. Taking these parameters together with $c_0 < 0$, such that the harmonic-oscillator ground state were to coincide with the physical mass of the pion of $m_\pi = 140$ MeV, the fall-off of the point-form spectator model form factor would be unreasonably strong. With $c_0 = 0$, on the other hand, the pion ground-state mass would be larger than 1 GeV and the fall-off of the form factor would be much too slow [BSFK09]. We have therefore tried to take the set of parameters of $a = 312$ MeV, $c_0 = -1.04$ GeV^2 and $m_\mathrm{q} = 340$ MeV, which have been already discussed in Sec. 6.2. These are reasonable values for the purpose of a qualitative comparison between our ap-

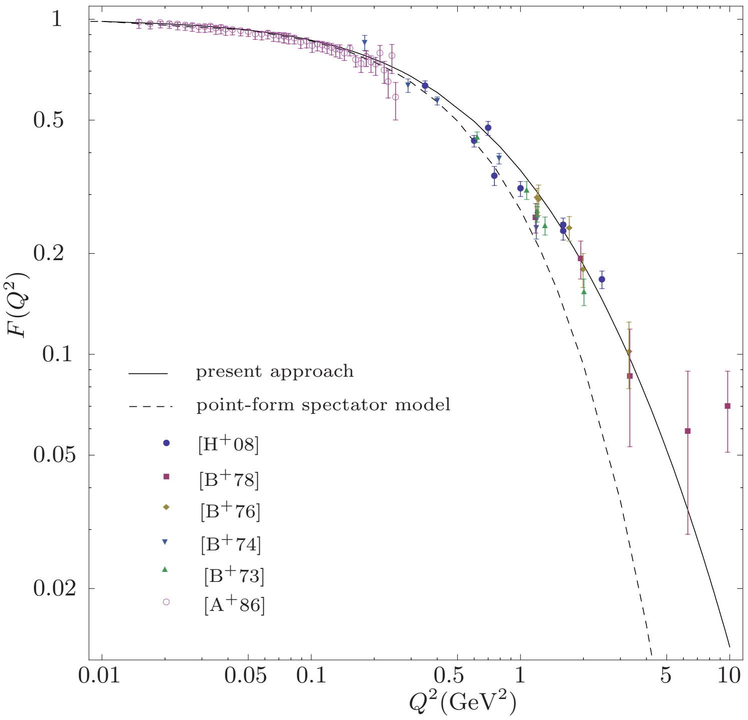

Figure 7.5: The electromagnetic pion form factor $F\left(Q^2\right)$ as evaluated by means of Eq. (5.25) with parameters $m_{\mathrm{q}} = 340\,\mathrm{MeV}$ and $a = 312\,\mathrm{MeV}$ in comparison with the outcome of the point-form spectator model with the same parameters and $m_{00} = 770\,\mathrm{MeV}$ [BSFK09]. Data are taken from Refs. [A+86, B+73, B+76, B+74, B+78, H+08].

proach and the point-form spectator model predictions. In Fig. 7.5 we compare our result with the point-form spectator model prediction and experimental data. Both results become comparable at small momentum transfers. Above $Q^2 \approx 1$ GeV^2, however, significant differences can be observed. These differences resemble the situation for the electromagnetic nucleon form factors. In the latter case the stronger fall-off produced by the point-form spectator model is a welcome feature which brings the theoretical predictions from constituent quark models close to experiments [MBC+07]. For the usual front-form spectator current in the $q^+ = 0$ frame agreement with experiment is achieved only by introducing electromagnetic form factors for the constituent quarks [Sim01]. It remains to be seen whether the situation for the electromagnetic pion form factor could also change in favor of the point-form spectator model if a more sophisticated quark-antiquark potential is employed which reproduces the mass of the pion and its lowest excitations sufficiently accurately [BSFK09].

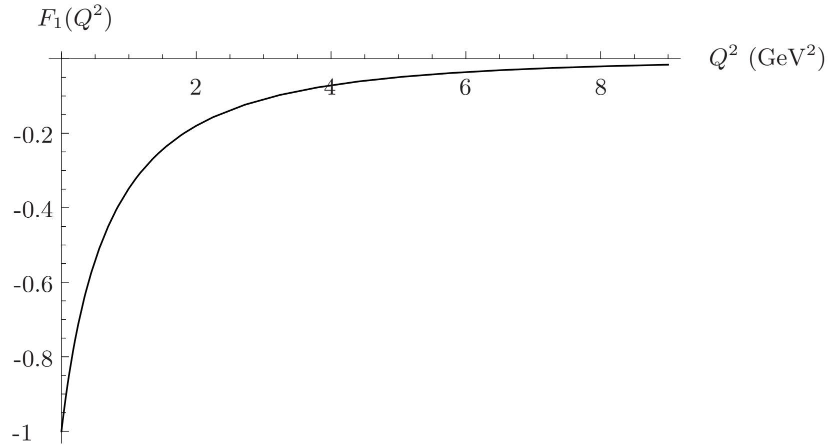

Figure 7.6: The electromagnetic ρ-meson form factor $F_1\left(Q^2\right)$ evaluated by means of Eq. (5.48) with $F_1^1(Q^2) + F_1^2(Q^2) = 1$ and $F_2^1(Q^2) = F_2^2(Q^2) = 0$ and parameters $m_{\mathrm{q}} = 340\,\mathrm{MeV}$, $a = 312\,\mathrm{MeV}$ and $c_0 = -1.04\,\mathrm{GeV}^2$ such that $m_{00} = 770\,\mathrm{MeV}$.

7.2 Electromagnetic ρ-Meson Form Factors

7.2.1 Discussion and Predictions

A charged $\rho^\pm$ meson in a constituent quark model is considered to be a quark-antiquark bound state with total spin $j = 1$. As for the pion the confining interaction between the quarks is modeled by the simple harmonic-oscillator potential of Sec. 6.2. We have fixed the 3 parameters $a = 312$ MeV, $c_0 = -1.04$ GeV^2 and $m_{\mathrm{q}} = 340$ MeV via the vector-meson spectrum, therefore the mass of the ground state $m_{00} = 770$ MeV coincides already with the correct ρ-meson mass m_ρ.

The ρ-meson electromagnetic form factors are computed by simply plugging the ground-state harmonic-oscillator wave function u_{00} and the ground-state mass m_{00} into the form factor expressions Eqs. (5.48), (5.49) and (5.50) with $F_1^1(Q^2) + F_1^2(Q^2) = 1$ and $F_2^1(Q^2) = F_2^2(Q^2) = 0$ (since the quarks are considered as point-like). The results are depicted in Figs. 7.6-7.8. By means of Eqs. (5.65) and (5.66) we obtain from $F_1\left(Q^2\right)$, $F_2\left(Q^2\right)$ and $G_{\mathrm{M}}\left(Q^2\right)$ the electric charge and quadrupole form factors of the ρ meson, $G_{\mathrm{C}}\left(Q^2\right)$ and $G_{\mathrm{Q}}\left(Q^2\right)$, respectively. They are plotted in Figs. 7.9 and 7.10. From Fig. 7.9 we read off the correct ρ^+-meson charge $G_{\mathrm{C}}(0) = 1$ in units of the fundamental charge $|\,\mathrm{e}\,|$. This is ensured only by the decomposition of the ρ-meson current given in Eq. (5.7), which justifies this particular way of separating the physical from the unphysical contributions. Our predictions for the magnetic dipole and the electric quadrupole moment given by the $Q^2 \to 0$ limits of $G_{\mathrm{M}}\left(Q^2\right)$ and $G_{\mathrm{Q}}\left(Q^2\right)$, cf. Eqs. (5.68) and (5.69), are $\mu_\rho = 2.2$ and $Q_\rho = -0.47$ (in units $|\,\mathrm{e}\,|/2m_\rho$ and $|\,\mathrm{e}\,|/m_\rho^2$), respectively.

From the form factors $G_{\mathrm{C}}(Q^2)$, $G_{\mathrm{M}}(Q^2)$ and $G_{\mathrm{Q}}(Q^2)$ we obtain the elastic scattering observables $A(Q^2)$, $B(Q^2)$ and $T_{20}(Q^2)$ by means of Eqs. (5.70),

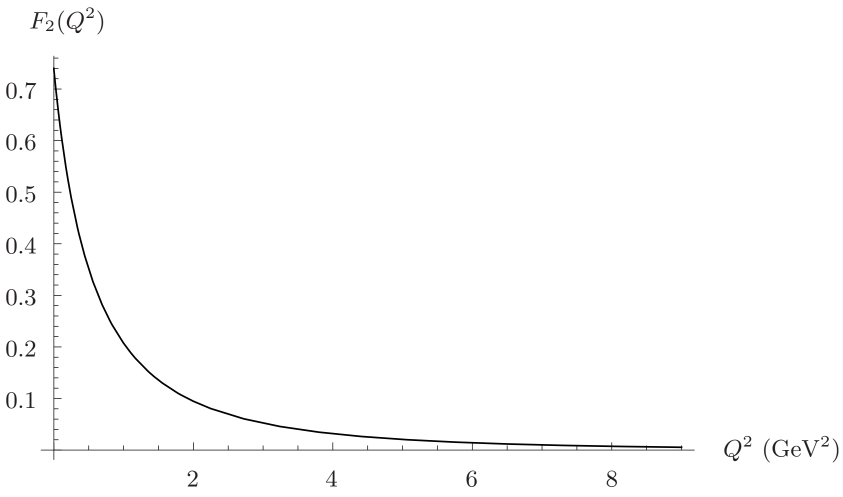

Figure 7.7: The electromagnetic ρ-meson form factor $F_2\left(Q^2\right)$ evaluated by means of Eq. (5.49) with $F_1^1(Q^2) + F_1^2(Q^2) = 1$ and $F_2^1(Q^2) = F_2^2(Q^2) = 0$ and with the same parameters as in Fig. 7.6.

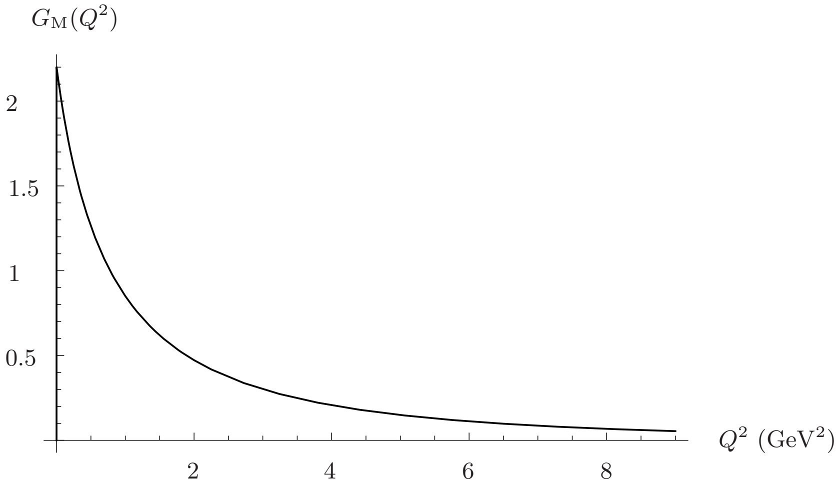

Figure 7.8: The magnetic ρ-meson form factor $G_{\mathrm{M}}\left(Q^2\right)$ evaluated by means of Eq. (5.50) with $F_1^1(Q^2) + F_1^2(Q^2) = 1$ and $F_2^1(Q^2) = F_2^2(Q^2) = 0$ and with the same parameters as in Fig. 7.6.

(5.71) and (5.72), respectively. The corresponding results are depicted in Figs. 7.11, 7.12 and 7.13.

It is also interesting to see how large the spurious contributions to the ρ-meson current are. In particular we shall concentrate on the violation of current conservation, the violation of the angular condition and the spurious form factor $B_6(Q^2)$, cf. Sec. 5.3.3. The ρ-meson current is not conserved due to a non-

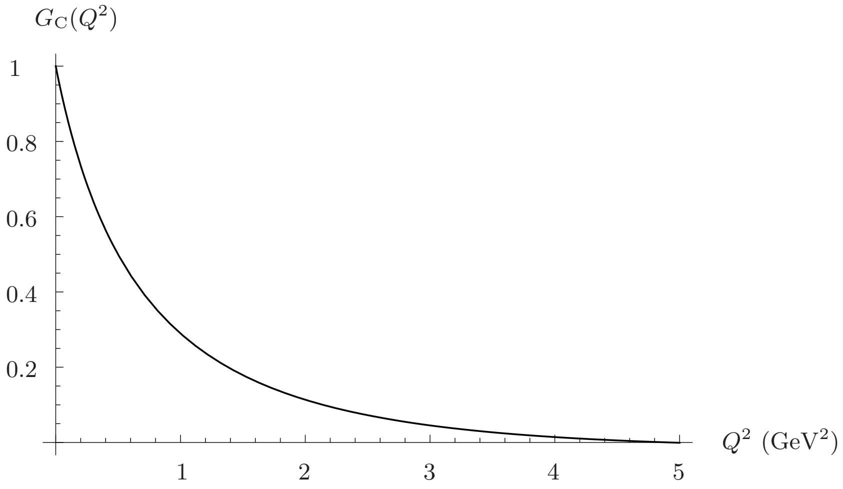

Figure 7.9: The electric charge ρ-meson form factor $G_C\left(Q^2\right)$ calculated from Eq. (5.65) with the same parameters as in Fig. 7.6.

vanishing current component $J^1_{10}(Q^2)$. For our standard kinematics, Eq. (5.11), its magnitude is depicted in Fig. 7.14. We also give our result for the violation of the angular condition, which is equal to the sum of the spurious form factors B_5 and B_7 (cf. Eq. (5.63)). The result is plotted in Fig. 7.15. Finally we calculate the spurious form factor $B_6(Q^2)$ from the difference of G_M and the expression Eq. (5.64). It is shown in Fig. 7.16. As one observes, the spurious contributions can contribute significantly to the current matrix elements and their separation is crucial for the extraction of meaningful physical form factors.

7.2.2 Comparisons

In order to make reasonable comparisons with other approaches to ρ-meson form factors we look, in particular, at calculations that have also used the simple harmonic-oscillator potential of Sec. 6.2: the light-front approach of Ref. [CJ04], the covariant extension of the light-front formalism of Ref. [Jau03], the covariant light-front prescription of Ref. [CDKM98] (the results from this prescription using a Gaussian wave function can be found in Ref. [Jau03]) and the standard light-front prescription of Ref. [CPCK88] (the results from this prescription can be found in Ref. [Jau03]). In order to end up with qualitative comparable results we adopt the values for the 2 parameters m_q and a of each approach and use them in our prescription. The predictions for the magnetic dipole moment μ_ρ and the electric quadrupole moment Q_ρ are compared in Tab. 7.1. It turns out that our results for μ_ρ and Q_ρ show agreement with the results of Carbonell et al., Ref. [CDKM98]. This is just what we expected due to the similarities and correspondences in both approaches. Our value for Q_ρ also coincides with the approach of Jaus, Ref. [Jau03], however the values for μ_ρ differ significantly. Quite good agreement is found with Chung et al., Ref. [CPCK88]. In particular, their value for μ_ρ is about 0.0434 units of $|\,\mathrm{e}\,|/2m_\rho$ lower than ours which coincides exactly with the value of $B_6(0)-B_5(0)-B_7(0)$. This difference

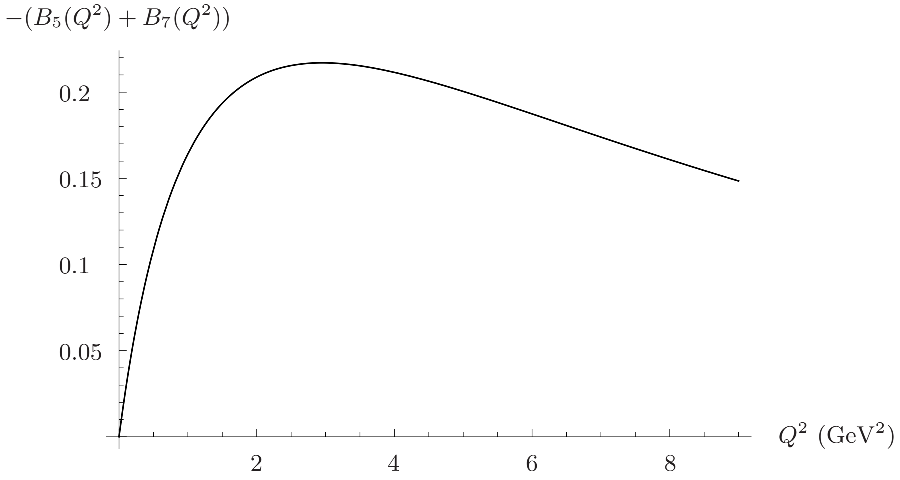

Figure 7.15: The violation of the angular condition for the ρ-meson given by Eq. (5.63) calculated with the same parameters as in Fig. 7.6.

between our value for the magnetic moment and theirs can be understood as the spurious term $-B_6(Q^2)+(B_5(Q^2)+B_7(Q^2))/(1+\eta))$ which is added to the magnetic form factor when using the standard light-front prescription of Ref. [CPCK88] (cf. Ref. [CDKM98]).

In Tab. 7.2 we also give our predictions for μ_ρ and Q_ρ in comparison with predictions of other approaches which use different model wave functions. Our predicted μ_ρ and Q_ρ have quite reasonable values which are lying between those of other approaches. In Tab. 7.3 we compare our approach with the work by

Table 7.4: Comparison of the ρ-meson form factors in various approaches.

Choi et al., Ref. [CJ04] using the harmonic-oscillator potential with the same parameters as therein. Here it turns out that best agreement is achieved for the magnetic form factor G_M.

In Tab. 7.4 we compare our prediction for the ρ-meson form factors with those of other approaches which use different model wave functions. First we observe that our electric charge form factor G_C lies for small values of Q^2 above the predictions of other approaches. For higher Q^2 our values for G_C lie somewhere between the values of the other approaches. Second, our magnetic form factor G_M lies above the values of other approaches in the whole range of Q^2. Third, our prediction for the electric quadrupole form factor G_Q lies between the ones of other approaches.

To conclude, in view of the simplicity of our harmonic-oscillator confining potential these are altogether quite reasonable results for our electromagnetic ρ-meson form factor.

7.3 Electromagnetic Deuteron Form Factors

In the present work we model the nucleon-nucleon interaction by the Pauli-Villars regularized Walecka-type potential which we have proposed in Sec. 6.3. For simplicity we have restricted ourselves to the static limits for the meson-exchange potential. However, we have refined our bound-state problem by replacing the non-relativistic by the relativistic kinetic-energy operator. To get numerical results for the deuteron form factors we plug the solution u_{00} and the mass eigenvalue $m_{00} = m_{\mathrm{D}}$ of the Walecka-model mass eigenvalue equation (6.33) into the expressions for the spin-1 form factors Eqs. (5.48), (5.49) and (5.50). In the present work we do not derive expressions for the nucleon form factors $F_1^{\mathrm{p}}(Q^2)$, $F_1^{\mathrm{n}}(Q^2)$, $F_2^{\mathrm{p}}(Q^2)$ and $F_2^{\mathrm{n}}(Q^2)$ but we rather use the 2 parametrizations for the nucleon form factors proposed in Refs. [GK92] and [MMD96]. For comparison, we also consider point-like nucleons, i.e. $F_1^{\mathrm{p}}(Q^2) = 1$ and $F_1^{\mathrm{n}}(Q^2) = F_2^{\mathrm{p}}(Q^2) = F_2^{\mathrm{n}}(Q^2) = 0$. The electromagnetic deuteron form factors $F_1\left(Q^2\right)$, $F_2\left(Q^2\right)$ and $G_{\mathrm{M}}\left(Q^2\right)$ are then evaluated with these 3 parametrizations. They are depicted in Figs. 7.17, 7.18 and 7.19, respectively. With the help of Eqs. (5.65) and (5.66) we obtain from $F_1\left(Q^2\right)$, $F_2\left(Q^2\right)$ and $G_{\mathrm{M}}\left(Q^2\right)$ the electric charge and quadrupole form factors of the deuteron, $G_{\mathrm{C}}(Q^2)$ and $G_{\mathrm{Q}}(Q^2)$, respectively. The correct charge $G_{\mathrm{C}}(0) = -F_1(0) = 1$ can be read off from Fig. 7.17, which is, in general, guaranteed only by the particular decomposition of the deuteron current given by Eq. (5.7). Our predictions for the magnetic dipole moment μ_{D} and the electric quadrupole moment Q_{D} defined by the $Q^2 \to 0$ limits of $G_{\mathrm{M}}\left(Q^2\right)$ and $G_{\mathrm{Q}}\left(Q^2\right)$ are summarized in Tab. 7.5.

Due to the simplicity of our Walecka-type model we do not expect to get form factor results that are close to experimental data. Therefore we do not compare our results with data, which is anyway not the purpose of this work.

[GK92] and [MMD96] and for point-like nucleons.

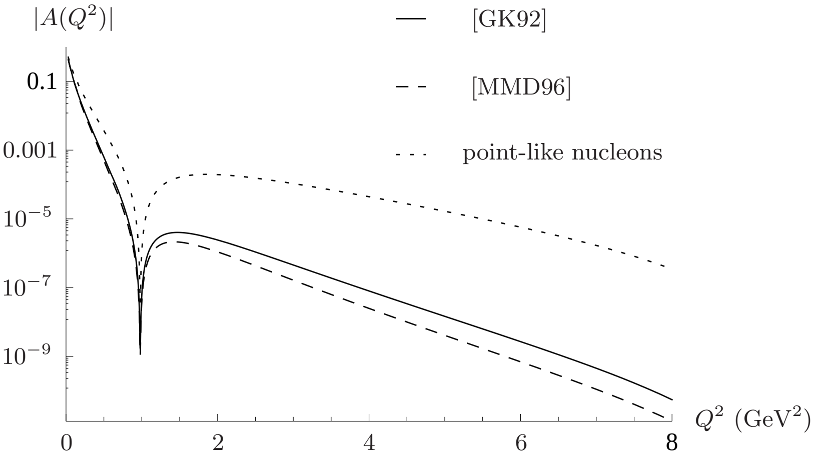

Figure 7.20: The elastic scattering observable $A(Q^2)$ of the deuteron evaluated within the Walecka-type model together with 2 different parametrizations for the nucleon form factors taken from Refs. [GK92] and [MMD96] and for point-like nucleons.

We should mention, however, that we find a quite reasonable value for the magnetic dipole moment μ_{D}. The value for point-like nucleons, e.g. comes close to the value $\mu_{\mathrm{D}} = 2$ for point-like spin-1 particles. Our results for the electric quadrupole moment Q_{D} are quite small as a consequence of the absence of a d-wave contribution. In the absence of a d-wave contribution the non-vanishing of Q_{D} is a pure relativistic effect.

From the form factors G_{C}, G_{M} and G_{Q} we obtain the elastic scattering observables $A(Q^2)$, $B(Q^2)$ and $T_{20}(Q^2)$ by means of Eqs. (5.70), (5.71) and (5.72), respectively. We compare the results for different parametrizations of the nucleon form factors in Figs. 7.20, 7.21 and 7.22.

Finally, it is quite interesting to look at the spurious contributions to the deuteron current causing violation of continuity, violation of the angular condition and the spurious form factor $B_6(Q^2)$. To this end we use the parametrization for the nucleon form factors of Ref. [MMD96] and compare it to the point-like nucleon case. The continuity-violating matrix element of the current is $J^1_{10}(Q^2)$ (with our standard kinematics). It is depicted in Fig. 7.23. In Fig. 7.24

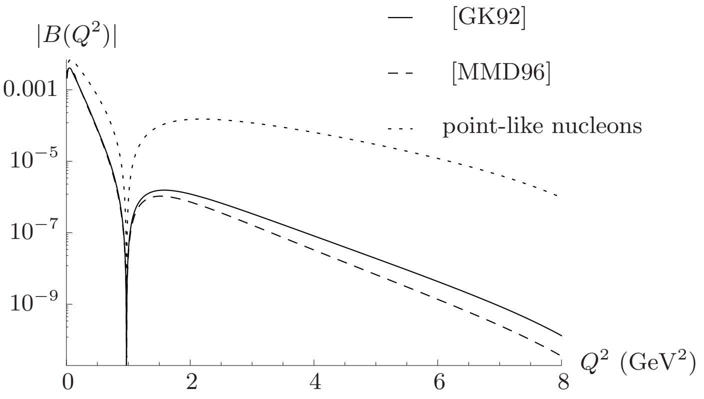

Figure 7.21: The elastic scattering observable $B(Q^2)$ of the deuteron evaluated within the Walecka-type model together with 2 different parametrizations for the nucleon form factors taken from Refs. [GK92] and [MMD96] and for point-like nucleons.

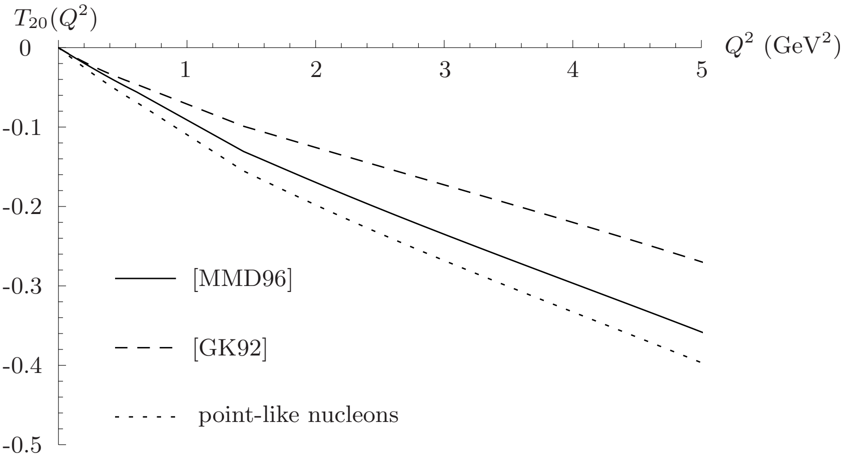

Figure 7.22: The elastic scattering observable $T_{20}(Q^2)$ of the deuteron evaluated within the Walecka-type model together with 2 different parametrizations for the nucleon form factors taken from Refs. [GK92] and [MMD96] and for point-like nucleons.

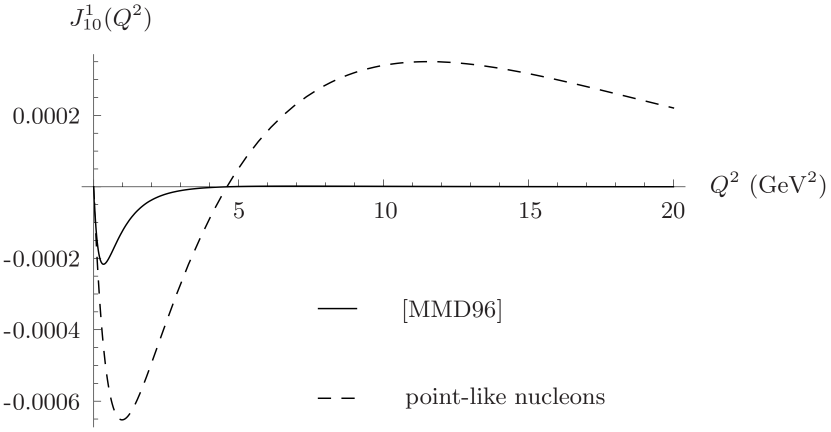

Figure 7.23: The violation of current conservation given by $J^1_{10}(Q^2)$ with our standard kinematics of momentum transfer in the 1-direction calculated within the Walecka-type model together with the nucleon form factor parametrization of Ref. [MMD96] and for point-like nucleons (here depicted in units of the elementary charge e) .

we show the violation of the angular condition which is equal to the sum of the spurious form factors $B_5(Q^2) + B_7(Q^2)$. The spurious form factor $B_6(Q^2)$, which is contained in the magnetic form factor extracted from the plus component of the current in the standard light-front prescription [CPCK88,CDKM98], is plotted in Fig. 7.25. What we observe is that the relative importance of spurious contributions diminishes if one goes from the strongly bound q$\bar{\text{q}}$ system to the weakly bound two-nucleon system. The influence of spurious contributions is further reduced by the nucleon form factors.

We should stress once more that the purpose of the above computation of the deuteron form factors within the simple Walecka-type model is not to find best agreement with experimental data. The calculation is rather part of the benchmark about relativistic effects in few-body physics, where different approaches to deuteron form factors are compared on equal grounds starting with the same fully covariant Walecka-model Lagrangean. Therefore, in order to make concise statements about our deuteron form factor results the findings of the other approaches participating in the benchmark are required.

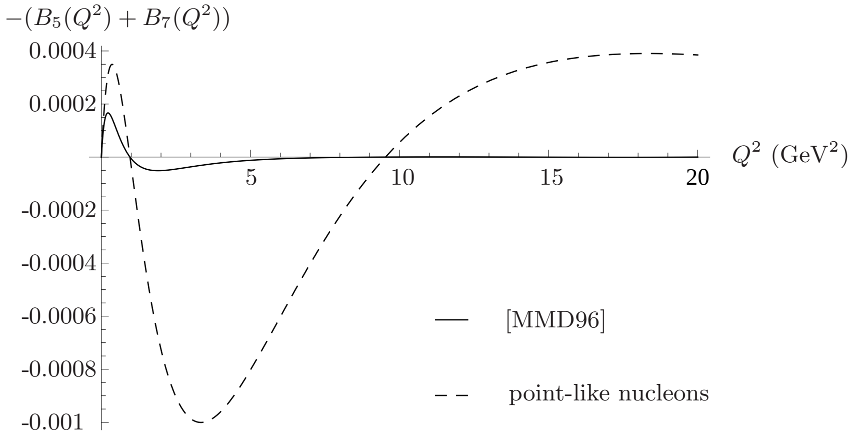

Figure 7.24: The violation of the angular condition for the ρ meson given by the sum of the spurious form factors $B_5(Q^2)$ and $B_7(Q^2)$. Here it is calculated within the Walecka-type model together with the nucleon form factor parametrization of Ref. [MMD96] and for point-like nucleons.

Chapter 8

Summary and Outlook

8.1 Summary

Of the various forms of relativistic dynamics given by Dirac, the point form is the least utilized, although it has several advantageous properties. The key benefit of the point form is the property that the Lorentz group is its kinematic group implying that only the Abelian group of space-time translations is affected by interactions. This natural way of separating the kinematic from the dynamic Poincaré generators allows for a manifest Lorentz covariant formulation of dynamical equations and makes for a simple behavior under Lorentz transformations.

In the present work we exploit the virtues of point-form relativistic quantum mechanics to analyze the electromagnetic properties of relativistic two-body systems. To this end we treat the elastic electromagnetic scattering of an electron by a bound-state as a two-channel problem for a Bakamjian-Thomas type mass operator. The 2 channels are coupled by appropriately defined electromagnetic vertex operators, which are constructed from quantum field theoretical Lagrangean densities. These vertex interactions describe the emission and absorption of a photon by the electron or the constituents of the bound state and they have the Lorentz structure of a field theoretical vertex. In this way the dynamics of the exchanged photon is taken explicitly into account. These vertices are, however, non-local due to the conservation of the overall four-velocity of the electron-bound-state(-photon) system that is inherent to the point-form Bakamjian-Thomas framework. Four-velocity conservation at the vertex is a necessary approximation in order to be able to formulate electron-bound-state scattering as a simple eigenvalue problem for a Bakamjian-Thomas type mass operator.

In this work we consider, for simplicity, only instantaneous interactions between the constituents forming the bound state. Instantaneous interactions can be used within the Bakamjian-Thomas framework without losing Poincaré invariance. Therefore, our approach preserves Poincaré invariance by construction. What we violate, however, within a Bakamjian-Thomas construction for more than 2 particles is macroscopic locality (i.e. cluster separability).

By a Feshbach reduction the eigenvalue problem for the coupled-channel mass operator can be brought into the form of a non-linear eigenvalue problem which defines the one-photon-exchange optical potential. As expected, the optical potential is a contraction of the (point-like) electron current with a bound-state current times the covariant photon propagator. The resulting bound-state current, which is expressed in terms of bound-state wave functions and constituent currents, is Hermitean and transforms covariantly under Lorentz transformations. Its Lorentz structure is, however, not fully determined by the incoming and outgoing bound-state momenta and spins. It turns out that additional, unphysical Lorentz covariant terms are needed to parametrize the current. These spurious contributions depend on the momentum of the electron and are the consequence of the violation of cluster separability in the Bakamjian-Thomas framework. Furthermore, both the physical and the spurious form factors (associated with the spurious contributions) depend not only on Mandelstam t, i.e. the four-momentum transfer squared, but also exhibit an additional dependence on Mandelstam s, i.e. the total invariant mass squared of the electron-bound-state system. These are the only independent Lorentz invariants that can be constructed from the incoming and outgoing bound-state and electron momenta.

In the present work we consider, in particular, spin-0 bound systems like the pion, and spin-1 bound systems like the ρ meson and the deuteron. The current we obtain for the case of a spin-0 bound state is conserved. It can be parametrized by 2 form factors, a physical and a spurious form factor. The structure of our current reveals an interesting correspondence between our approach and the covariant light-front approach [KS94, CDKM98]. Their current also contains a spurious contribution which is, in their case, associated with an arbitrary light-like four-vector ω that describes the orientation of the light front. The dependence on this light-front orientation is a consequence of retaining explicit Lorentz covariance in the light-front approach.

We observe that the s-dependence of our physical form factor vanishes rather quickly with increasing s, which suggests taking the limit s → ∞ to obtain a sensible physical form factor that depends only on Mandelstam t. At the same time the spurious form factor is seen to vanish, implying that taking the limit s → ∞ removes all cluster-separability-violating effects. The current in the limit is a one-body current. The limit of letting the bound-state momentum go to infinity can be understood as considering only the subprocess where the photon is absorbed or emitted by the bound state in the infinite-momentum frame of the bound state. Therefore, it is not too surprising that in this limit we have been able to prove that our analytical formula for the form factor coincides with the standard front-form expression that is extracted from the plus component of a spectator current in the $q^+ = 0$ frame [CCP88]. With regard to the similarities of our approach and the covariant light-front approach this is quite obvious: in the standard-light front dynamics, with the fixed light front vector $\omega = (1, 0, 0, -1)$, the plus component of the current does not contain any spurious contributions (since $\omega^+ = 0$).

As in the scalar case, the Lorentz structure of our spin-1 bound-state current (which contains 3 physical and 8 spurious contributions) resembles the corresponding current of the covariant light-front dynamics if the sum of the incoming and outgoing electron momenta is identified with the light-front vector ω. However, unlike the spin-0 case, by taking the limit s → ∞, only 4 spurious contributions proportional to ω are removed. The remaining 4 contributions are responsible for the violation of current conservation and for the violation of the angular condition. This again resembles the situation of covariant light-front dynamics after fixing ω to the standard value $\omega = (1, 0, 0, -1)$. The plus component of the spin-1 spectator current (from which the form factors are usually extracted) then still contains 4 spurious contributions leading to the violation of the angular condition. There is, however, an unambiguous prescription proposed by Karmanov and Smirnov [KS94] for how to separate the physical from the unphysical contributions, which can be directly applied to our case.

For mesons, we model the confining interaction between the quark and the antiquark by a simple harmonic-oscillator potential. Our numerical results for the ρ-meson magnetic dipole moment and electric quadrupole moment are, as expected, in agreement with the results obtained from the covariant light-front prescription (using the same model). The results for the magnetic dipole moment obtained from the standard front-form prescription (using the same model) differ from our results exactly by the value of the spurious contribution that is contained in the magnetic form factor obtained from the standard, non-covariant light-front prescription.

For the deuteron we propose a simple Walecka-type model based on a Lagrangean density for a field theoretical description of nucleons that interact via scalar σ- and vector ω-exchange. This model is intended to serve as a common starting point for a benchmark calculation on 'relativistic effects in few-body physics'. The aim is to identify and compare such effects in different relativistic approaches to few-body systems by means of the deuteron structure. We have fixed the free parameters of the model such that the experimental values for the binding energy of the deuteron and the triplet scattering length are reasonably well reproduced in the non-relativistic limit. In order to go beyond the non-relativistic limit we have included Pauli-Villars regulators. The simplest quantity we can derive is the so-called *body form factor*, which is just the Fourier transform of the charge distribution. All calculations within this thesis use the static approximation to this Walecka-type one-boson exchange nucleon-nucleon interaction. As a consequence the deuteron is a pure s-wave. Nevertheless it is possible to study several relativistic effects. The first is the change of the body form factor that occurs if the non-relativistic kinetic energy is replaced by the corresponding relativistic expression. This affects the wave function and in the sequel the body form factor. As a next step we have plugged this "relativized" deuteron wave function into our point-form expression for the deuteron current and the form factors. Here Wigner rotations and further relativistic kinematical factors come into play. Due to the covariance of the deuteron current not only one, but 3 form factors are found. The body form factor then corresponds to the electric monopole form factor G_{C}. We observe that cluster-separability violating effects are less important in the weakly bound deuteron than in the strongly bound ρ meson.

To summarize, we have presented a relativistic formalism which makes it possible to derive the electromagnetic currents and form factors of bound few-body systems consistent with the binding forces. One advantage of this approach is that the bound-state current is uniquely determined by the interaction dynamics which is responsible for the binding. Furthermore, the current can directly be extracted from the one-photon-exchange optical potential. However, in using a Bakamjian-Thomas approach, problems involving cluster separability arise which manifest themselves by unphysical contributions to the current. Nevertheless, we have found an unambiguous procedure for how to separate them from the physical contributions to get meaningful results for the form factors.

8.2 Outlook

Our coupled-channel formalism for calculating form factors is quite general and can be applied immediately to other few-body systems. In Refs. [GRS10,GRS11] for example, the present formalism has been applied to calculate electromagnetic and weak form factors of heavy-light systems. Therein, a simple analytical expression for the Isgur-Wise function [IW89,IW90] has been found in the heavy-quark limit.

The above formalism can also be generalized in different directions. A next step to full relativity would be to account for dynamical particle-exchange interactions by adding additional channels. In particular, for the Walecka-type model one could make the σ- and ω-exchange dynamical. This would add meson-exchange contributions to the spectator current that results from instantaneous binding forces. Corresponding extensions of the point-form approach are under investigation. In general, the construction of such many-body currents is a highly nontrivial task [GR87]. It remains to be seen how large the effects of such additional exchange-current contributions on the form factors are. Furthermore, due to the generality of our approach, applications to bound systems with half-integer spins such as baryons or other nuclei seem to be straightforward.

Altogether, the approach of this thesis offers the possibility to be further refined and generalized and to be applied to various problems of relativistic few-body physics.

Appendix A

Minkowski Space

A.1 Conventions and Basic Relations

We define a contravariant four-vector by

$$x^{\mu} := (x^0, x^1, x^2, x^3) = (x^0, \boldsymbol{x}) \,. \tag{A.1}$$

The corresponding covariant vector is defined by

$$x_{\mu} := (x_0, x_1, x_2, x_3) = (x^0, -\boldsymbol{x}) = \mathrm{g}_{\mu\nu} x^{\nu} \tag{A.2}$$

with the metric tensor

$$\mathrm{diag}\,(\mathrm{g}_{\mu\nu}) = (1, -1, -1, -1) \,. \tag{A.3}$$

Throughout the present thesis we use Einstein's sum convention meaning that a sum over repeated indices is always assumed. Greek indices like $\mu, \nu, \tau, \ldots$ on four-vectors $\{x^{\mu}\} \equiv x$ vary from 0 to 3 and Roman indices like $i, j, k, \ldots$ on three-vectors $\{x^i\} \equiv \boldsymbol{x}$ vary from 1 to 3.

The invariant scalar product between 2 four-vectors x^{μ} and y^{μ} is defined by

$$x \cdot y := x^{\mu} \mathrm{g}_{\mu\nu} y^{\nu} = x^0 y^0 - \boldsymbol{x} \cdot \boldsymbol{y} \,. \tag{A.4}$$

This scalar product is invariant under the Lorentz transformation

$$x^{\mu} \xrightarrow{\Lambda} x'^{\mu} = \Lambda^{\mu}{}_{\nu} x^{\nu} \tag{A.5}$$

if the matrices Λ^{μ}_{ν} satisfy a generalized orthogonality relation

$$\Lambda^{\mu}{}_{\nu} \Lambda^{\sigma}{}_{\tau} \mathrm{g}^{\nu\tau} = \mathrm{g}^{\mu\sigma}. \tag{A.6}$$

This relation can be rewritten as

$$\Lambda^{\mu}{}_{\nu} \Lambda_{\sigma}{}^{\nu} = \mathrm{g}^{\mu}_{\sigma} \equiv \delta^{\mu}_{\sigma} \tag{A.7}$$

which implies that

$$\Lambda_{\sigma}{}^{\nu} = (\Lambda^{-1})^{\nu}{}_{\sigma} \,. \tag{A.8}$$

A.2 Matrix Representation of the Poincaré Group

In order to find a matrix representation for the inhomogeneous part of the Poincaré group, we go over to homogeneous coordinates defined by the five-component vectors [Sch01]

$$\xi^{\eta} := \left(\xi^4 x^0, \xi^4 x^1, \xi^4 x^2, \xi^4 x^3, \xi^4\right) . \tag{A.9}$$

Then a Poincaré group element is given by the (5×5)-matrix

$$\varPi\left(\varLambda, a\right) := \begin{pmatrix} \varLambda^{\mu}_{\ \nu} & a^{\mu} \\ 0^{\mathrm{T}\nu} & 1 \end{pmatrix} \tag{A.10}$$

and a Poincaré transformation can be written in the homogeneous form

$$\xi'^{\eta} = \varPi^{\eta}_{\ \theta}\xi^{\theta} \quad \text{with} \quad \eta, \theta = 0, \ldots, 4\,. \tag{A.11}$$

Consequently, a Lorentz transformation and a space-time translation are given by

$$\varPi\left(\varLambda, 0\right) := \begin{pmatrix} \varLambda^{\mu}_{\ \nu} & 0^{\mu} \\ 0^{\mathrm{T}\nu} & 1 \end{pmatrix} \quad \text{and} \quad T\left(a\right) := \varPi\left(1_{4\times 4}, a\right) , \tag{A.12}$$

respectively. Writing $T\left(a\right)$ in exponential form as $T\left(a\right) = \exp\left(-\mathrm{i}\, a_{\mu} P^{\mu}\right)$ the generators P^{μ} for infinitesimal space-time translations, being (5×5)-matrices, are defined by

$$P^{\mu} := \mathrm{i}\, \mathrm{g}^{\mu\nu} \frac{\partial T\left(a\right)}{\partial a^{\nu}}\bigg|_{a^{\nu}=0} . \tag{A.13}$$

Appendix B

Spinors and Polarization Vectors

B.1 Spin-1/2 Dirac Particles

B.1.1 Dirac Representation

We use the standard (Dirac) representation of the Dirac matrices given by

$$\gamma^0 = \begin{pmatrix} 1_2 & 0 \\ 0 & -1_2 \end{pmatrix} , \quad \boldsymbol{\gamma} = \begin{pmatrix} 0 & \boldsymbol{\sigma} \\ -\boldsymbol{\sigma} & 0 \end{pmatrix} = \gamma^0 \boldsymbol{\alpha} \tag{B.1}$$

and

$$\gamma^5 = \begin{pmatrix} 0 & 1_2 \\ 1_2 & 0 \end{pmatrix} . \tag{B.2}$$

Here

$$\sigma_1 = -\sigma^1 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} , \quad \sigma_2 = -\sigma^2 = \begin{pmatrix} 0 & -\mathrm{i} \\ \mathrm{i} & 0 \end{pmatrix}$$

and

$$\sigma_3 = -\sigma^3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} \tag{B.3}$$

are the usual Pauli matrices. A useful relation for the Pauli matrices is

$$(\boldsymbol{\sigma} \cdot \boldsymbol{a})\,(\boldsymbol{\sigma} \cdot \boldsymbol{b}) = 1_2\, \boldsymbol{a} \cdot \boldsymbol{b} + \mathrm{i}\, \boldsymbol{\sigma} \cdot (\boldsymbol{a} \times \boldsymbol{b}) \ . \tag{B.4}$$

Using this standard representation a canonical boost in the 4 × 4 matrix representation of the SL$(2, \mathbb{C})$, Eq. (2.25), has the form

$$S[\underline{B}_{\mathrm{c}}(\boldsymbol{v})] = \sqrt{\frac{p^0 + m}{2m}} \begin{pmatrix} 1_2 & \frac{\boldsymbol{\sigma}\cdot\boldsymbol{p}}{p^0+m} \\ \frac{\boldsymbol{\sigma}\cdot\boldsymbol{p}}{p^0+m} & 1_2 \end{pmatrix} \quad \text{with} \quad v := \frac{p}{m} \, . \tag{B.5}$$

The Dirac spinors for an (anti)particle at rest are given by

$$u_\sigma(\mathbf{0}) := \sqrt{2m} \begin{pmatrix} \varsigma_\sigma \\ 0 \end{pmatrix} \quad \text{and} \quad v_\sigma(\mathbf{0}) := -\sqrt{2m} \begin{pmatrix} 0 \\ \varepsilon\varsigma_\sigma \end{pmatrix} , \quad \sigma = \pm\frac{1}{2} \, , \tag{B.6}$$

where ς_σ is the two-component Pauli spinor

$$\varsigma_\sigma = \begin{pmatrix} \frac{1}{2} + \sigma \\ \frac{1}{2} - \sigma \end{pmatrix} \quad \text{and} \quad \varepsilon = \mathrm{i}\,\sigma_2 \,. \tag{B.7}$$

Here σ denotes the canonical spin projection on the 3-axis. The Pauli spinors are normalized according to $\varsigma_{\sigma'}^\dagger \varsigma_\sigma = \delta_{\sigma'\sigma}$. The spinors for an (anti)particle with momentum $p = mv$ are given by

$$u_\sigma(\boldsymbol{p})_\alpha = S_{\alpha\beta}\left[\underline{B}_{\mathrm{c}}(\boldsymbol{v})\right] u_\sigma(\boldsymbol{0})_\beta = \sqrt{p^0 + m} \begin{pmatrix} \varsigma_\sigma \\ \frac{\boldsymbol{\sigma}\cdot\boldsymbol{p}}{p^0+m}\varsigma_\sigma \end{pmatrix}_\beta , \tag{B.8}$$

$$v_\sigma(\boldsymbol{p})_\alpha = S_{\alpha\beta}\left[\underline{B}_{\mathrm{c}}(\boldsymbol{v})\right] v_\sigma(\boldsymbol{0})_\beta = -\sqrt{p^0 + m} \begin{pmatrix} \frac{\boldsymbol{\sigma}\cdot\boldsymbol{p}}{p^0+m}\varepsilon\varsigma_\sigma \\ \varepsilon\varsigma_\sigma \end{pmatrix}_\beta , \tag{B.9}$$

with $\alpha, \beta = 1, \ldots, 4$. We use the Greek letters α and β to denote Dirac indices. For equal particle and antiparticle masses the spinors $u_\sigma(\boldsymbol{p})$ and $v_\sigma(\boldsymbol{p})$ are related by [BD64, Nac86]

$$v_\sigma(\boldsymbol{p}) = C\bar{u}_\sigma^{\mathrm{T}}(\boldsymbol{p}) \quad \text{and} \quad u_\sigma(\boldsymbol{p}) = C\bar{v}_\sigma^{\mathrm{T}}(\boldsymbol{p}) \,, \tag{B.10}$$

where $C := i\gamma^2\gamma^0 = -C^{-1} = -C^\dagger = -C^{\mathrm{T}}$ is the charge conjugation operator. With $C{\gamma^\mu}^{\mathrm{T}}C^{-1} = -\gamma^\mu$ it follows immediately that

$$\bar{v}_\sigma(\boldsymbol{p})\,\gamma^\mu v_{\sigma'}(\boldsymbol{p}') = \left[\bar{u}_{\sigma'}(\boldsymbol{p}')\,\gamma^\mu u_\sigma(\boldsymbol{p})\right]^{\mathrm{T}} = \bar{u}_{\sigma'}(\boldsymbol{p}')\,\gamma^\mu u_\sigma(\boldsymbol{p}) \tag{B.11}$$

since $\bar{u}_{\sigma'}(\boldsymbol{p}')\,\gamma^\mu u_\sigma(\boldsymbol{p})$ is a scalar quantity.

B.1.2 Covariance Properties

Under a Lorentz transformation $\mathit{\Lambda}$ the spinor $u_\sigma(\boldsymbol{p})$ and its adjoint $\bar{u}_\sigma(\boldsymbol{p})$ transform according to [KP91]

$$\begin{aligned} u_\sigma(\boldsymbol{p}) &\xrightarrow{\mathit{\Lambda}} u_{\bar\sigma}(\boldsymbol{\mathit{\Lambda}}p) = D^{\frac{1}{2}}_{\sigma\bar\sigma}\left(\underline{R}^{-1}_{\mathrm{W_c}}(v,\mathit{\Lambda})\right) S(\underline{\mathit{\Lambda}})u_\sigma(\boldsymbol{p}) \,, \\ \bar{u}_\sigma(\boldsymbol{p}) &\xrightarrow{\mathit{\Lambda}} \bar{u}_{\bar\sigma}(\boldsymbol{\mathit{\Lambda}}p) = \bar{u}_\sigma(\boldsymbol{p})S^{-1}(\underline{\mathit{\Lambda}})D^{\frac{1}{2}*}_{\sigma\bar\sigma}\left(\underline{R}^{-1}_{\mathrm{W_c}}(v,\mathit{\Lambda})\right) \,, \end{aligned} \tag{B.12}$$

with $\sigma, \bar\sigma = \pm\frac{1}{2}$. Here we have used

$$S^\dagger(\underline{\mathit{\Lambda}})\gamma^0 = \gamma^0 S^{-1}(\underline{\mathit{\Lambda}}) \,. \tag{B.13}$$

The aim of this section is to find the transformation properties of the current of an extended massive spin-1/2 particle such as a nucleon. Such a current is given by

$$\begin{aligned} &J^\mu(\boldsymbol{p}', \sigma'; \boldsymbol{p}, \sigma) \\ &\quad = |\,\mathrm{e}\,|\,\bar{u}_{\sigma'}(\boldsymbol{p}')\left[F_1((p-p')^2)\gamma^\mu + F_2((p-p')^2)\frac{\mathrm{i}(p'-p)_\nu\sigma^{\mu\nu}}{2m}\right]u_\sigma(\boldsymbol{p}) \end{aligned} \tag{B.14}$$

where $\sigma^{\mu\nu} = \frac{\mathrm{i}}{2}(\gamma^\mu\gamma^\nu - \gamma^\nu\gamma^\mu)$ and e is the elementary charge. In our notation the anomalous magnetic moment κ of the spin-1/2 constituent (in units of the Bohr magneton) is absorbed into F_2 such that $F_2(0) = \kappa$. For point-like particles, such as quarks (electrons), the current simplifies by setting the Dirac form factor $F_1((p-p')^2) = Q_{\mathrm{q(e)}}$ and the Pauli form factor $F_2((p-p')^2) = 0$, where $Q_{\mathrm{q(e)}}$ is the electric charge of the corresponding quark (electron). For the first term in Eq. (B.14) we find, using the transformation properties of the spinors, Eq. (B.12), together with

$$S^{-1}(\underline{\Lambda})\gamma^\mu S(\underline{\Lambda}) = \Lambda^\mu{}_\nu \gamma^\nu \,, \tag{B.15}$$

the following transformation properties under a Lorentz transformation:

$$\begin{aligned}
&\bar{u}_{\sigma'}(\boldsymbol{p}')\gamma^\mu u_\sigma(\boldsymbol{p}) \xrightarrow{\Lambda} \bar{u}_{\bar{\sigma}'}(\boldsymbol{\Lambda}p')\gamma^\mu u_{\bar{\sigma}}(\boldsymbol{\Lambda}p) \\
&\quad = \quad \Lambda^\mu{}_\nu \bar{u}_{\sigma'}(\boldsymbol{p}')\gamma^\nu u_\sigma(\boldsymbol{p}) D^{\frac{1}{2}*}_{\sigma'\bar{\sigma}'}\left(\underline{R}^{-1}_{\mathrm{W_c}}(v',\Lambda)\right) D^{\frac{1}{2}}_{\sigma\bar{\sigma}}\left(\underline{R}^{-1}_{\mathrm{W_c}}(v,\Lambda)\right) \,.
\end{aligned} \tag{B.16}$$

For the $\sigma^{\mu\nu}$-part we use the transformation properties of the Dirac matrices $S^{-1}(\underline{\Lambda})\gamma^\mu\gamma^\nu S(\underline{\Lambda}) = \Lambda^\mu{}_\rho \gamma^\rho \Lambda^\nu{}_\sigma \gamma^\sigma$ to find

$$\begin{aligned}
&\bar{u}_{\sigma'}(\boldsymbol{p}')\sigma^{\mu\nu} u_\sigma(\boldsymbol{p}) \xrightarrow{\Lambda} \bar{u}_{\bar{\sigma}'}(\boldsymbol{\Lambda}p')\sigma^{\mu\nu} u_{\bar{\sigma}}(\boldsymbol{\Lambda}p) \\
&\quad = \Lambda^\mu{}_\rho \Lambda^\nu{}_\tau \bar{u}_{\sigma'}(\boldsymbol{p}')\sigma^{\rho\tau} u_\sigma(\boldsymbol{p}) D^{\frac{1}{2}*}_{\sigma'\bar{\sigma}'}\left(\underline{R}^{-1}_{\mathrm{W_c}}(v',\Lambda)\right) D^{\frac{1}{2}}_{\sigma\bar{\sigma}}\left(\underline{R}^{-1}_{\mathrm{W_c}}(v,\Lambda)\right) \,.
\end{aligned} \tag{B.17}$$

The whole term proportional to $\sigma^{\mu\nu}$ transforms in the same way as the γ^μ-part:

$$\begin{aligned}
&\bar{u}_{\bar{\sigma}'}(\boldsymbol{\Lambda}p')\frac{\mathrm{i}(\Lambda p' - \Lambda p)_\nu \sigma^{\mu\nu}}{2m} u_{\bar{\sigma}}(\boldsymbol{\Lambda}p) \\
&\quad = \quad \Lambda^\mu{}_\rho \Lambda^\nu{}_\tau \bar{u}_{\sigma'}(\boldsymbol{p}'))\frac{\mathrm{i}(\Lambda^{-1})^\lambda{}_\nu (p'-p)_\lambda \sigma^{\rho\tau}}{2m} u_\sigma(\boldsymbol{p}) \\
&\qquad\quad \times D^{\frac{1}{2}*}_{\sigma'\bar{\sigma}'}\left(\underline{R}^{-1}_{\mathrm{W_c}}(v',\Lambda)\right) D^{\frac{1}{2}}_{\sigma\bar{\sigma}}\left(\underline{R}^{-1}_{\mathrm{W_c}}(v,\Lambda)\right) \\
&\quad = \quad \Lambda^\mu{}_\rho \bar{u}_{\sigma'}(\boldsymbol{p}'))\frac{\mathrm{i}(p'-p)_\lambda \sigma^{\rho\lambda}}{2m} u_\sigma(\boldsymbol{p}) \\
&\qquad\quad \times D^{\frac{1}{2}*}_{\sigma'\bar{\sigma}'}\left(\underline{R}^{-1}_{\mathrm{W_c}}(v',\Lambda)\right) D^{\frac{1}{2}}_{\sigma\bar{\sigma}}\left(\underline{R}^{-1}_{\mathrm{W_c}}(v,\Lambda)\right) \,,
\end{aligned} \tag{B.18}$$

where we have used (by rewriting Eq. (A.6))

$$\Lambda^\mu{}_\nu \Lambda_\sigma{}^\nu = \mathrm{g}^\mu_\sigma = \delta^\mu_\sigma \quad \Rightarrow \quad \Lambda_\sigma{}^\nu = (\Lambda^{-1})^\nu{}_\sigma \,. \tag{B.19}$$

With these findings we are finally able to write down the transformation properties of a spin-1/2 current under Lorentz transformations:

$$\begin{aligned}
J^\mu(\boldsymbol{p}',\sigma';\boldsymbol{p},\sigma) \quad &\xrightarrow{\Lambda} \quad J^\mu(\boldsymbol{\Lambda}p',\bar{\sigma}';\boldsymbol{\Lambda}p,\bar{\sigma}) \\
&= \quad \Lambda^\mu{}_\nu J^\nu(\boldsymbol{p}',\sigma';\boldsymbol{p},\sigma) D^{\frac{1}{2}*}_{\sigma'\bar{\sigma}'}\left(\underline{R}^{-1}_{\mathrm{W_c}}(v',\Lambda)\right) D^{\frac{1}{2}}_{\sigma\bar{\sigma}}\left(\underline{R}^{-1}_{\mathrm{W_c}}(v,\Lambda)\right) \,.
\end{aligned} \tag{B.20}$$

B.1.3 Hermiticity

With the help of the relations

$$\gamma^0 \gamma^{\mu\dagger} \gamma^0 = \gamma^\mu \quad \text{and} \quad \gamma^0 \sigma^{\mu\nu\dagger} \gamma^0 = \sigma^{\mu\nu} \tag{B.21}$$

Hermiticity of the spin-1/2 current (B.14) is easily proved. To this end we look at the Hermitean conjugate of the current matrix:

$$\begin{aligned}
&[J^{\mu}(\boldsymbol{p}',\sigma';\boldsymbol{p},\sigma)]^{\dagger} \\
&\quad= [J^{\mu *}(\boldsymbol{p}',\sigma';\boldsymbol{p},\sigma)]^{\mathrm{T}} \\
&\quad= |\,\mathrm{e}\,|\, u^{\dagger}_{\sigma}(\boldsymbol{p}) \left[F_1((p-p')^2)\gamma^{\mu\dagger} - F_2((p-p')^2)\frac{\mathrm{i}(p'-p)_{\nu}\sigma^{\mu\nu\dagger}}{2m}\right]\gamma^0 u_{\sigma'}(\boldsymbol{p}') \\
&\quad= J^{\mu}(\boldsymbol{p},\sigma;\boldsymbol{p}',\sigma') \\
&\quad= J^{\mu *}(\boldsymbol{p}',\sigma';\boldsymbol{p},\sigma)\,, \qquad \text{(B.22)}
\end{aligned}$$

where we have used in the last step $J^{\mu *}(\boldsymbol{p}',\sigma';\boldsymbol{p},\sigma) = [J^{\mu *}(\boldsymbol{p}',\sigma';\boldsymbol{p},\sigma)]^{\mathrm{T}}$ since it is a scalar quantity.

B.2 Massless Spin-1 Particles

Appropriately orthonormalized photon polarization vectors $\epsilon^{\mu}_{\lambda}(\boldsymbol{p})$, which are most convenient for our purpose are given by the components of the helicity boost matrix $\epsilon^{\mu}_{\lambda}(\boldsymbol{p}) := B_{\mathrm{h}}(\boldsymbol{p})^{\mu}_{\ \lambda}$ [Kli03b]. They satisfy the usual completeness relation

$$\sum_{\lambda=0}^{3} \epsilon^{\mu}_{\lambda}(\boldsymbol{p})(-\mathrm{g}^{\lambda\lambda})\,\epsilon^{*\nu}_{\lambda}(\boldsymbol{p}) = -\mathrm{g}^{\mu\nu}\,. \qquad \text{(B.23)}$$

These photon polarization vectors transform under a Lorentz transformation according to

$$\epsilon^{\mu}_{\lambda}(\boldsymbol{p}) \xrightarrow{\Lambda} \epsilon^{\mu}_{\bar{\lambda}}(\boldsymbol{\Lambda} p) = R^{-1}_{\mathrm{W_h}}(p,\Lambda)_{\lambda\bar{\lambda}}\Lambda^{\mu}_{\ \nu}\epsilon^{\nu}_{\lambda}(\boldsymbol{p})\,. \qquad \text{(B.24)}$$

B.3 Massive Spin-1 Particles

B.3.1 Polarization Vectors

The polarization vectors $\epsilon^{\nu}_{\sigma}(\mathbf{0})$ of a spin-1 particle at rest with $\sigma = \pm 1, 0$ are usually defined by [AH03, Sca07]

$$\epsilon^{\nu}_{1}(\mathbf{0}) := -\frac{1}{\sqrt{2}}(0,1,\mathrm{i},0)^{\nu}\,, \qquad \text{(B.25)}$$

$$\epsilon^{\nu}_{-1}(\mathbf{0}) := \frac{1}{\sqrt{2}}(0,1,-\mathrm{i},0)^{\nu}\,, \qquad \text{(B.26)}$$

$$\epsilon^{\nu}_{0}(\mathbf{0}) := (0,0,0,1)^{\nu}\,. \qquad \text{(B.27)}$$

The boosted polarization vectors are obtained from the rest-frame vectors by a canonical boost with velocity $\boldsymbol{v} := \boldsymbol{p}/m$:

$$\epsilon^{\mu}_{\sigma}(\boldsymbol{p}) = B_{\mathrm{c}}(\boldsymbol{v})^{\mu}_{\ \nu}\epsilon^{\nu}_{\sigma}(\mathbf{0})\,. \qquad \text{(B.28)}$$

The transversality property then reads

$$\epsilon_{\sigma}(\boldsymbol{p}) \cdot p = 0\,. \qquad \text{(B.29)}$$

The transformation properties of the polarization vectors under Lorentz transformations are given by

$$\epsilon^\mu_\sigma(\boldsymbol{p}) \xrightarrow{\Lambda} \epsilon^\mu_{\bar\sigma}(\bar{\boldsymbol{p}}) = D^1_{\sigma\bar\sigma}\left(\underline{R}^{-1}_{\mathrm{W_c}}(v,\Lambda)\right)\Lambda^\mu{}_\nu\epsilon^\nu_\sigma(\boldsymbol{p})\,, \tag{B.30}$$

with $\sigma, \bar\sigma = \pm 1, 0$.

Polarization vectors of spin-1 particles which are described by velocity states $|V;\ldots;\boldsymbol{k}_j,\mu_j;\ldots\rangle$ transform under a Lorentz transformation with a Wigner rotation according to

$$\epsilon^\mu_{\mu_j}(\boldsymbol{k}_j) \xrightarrow{\Lambda} \epsilon^\mu_{\bar\mu_j}(\boldsymbol{R}_{\mathrm{W_c}}(V,\Lambda)k_j) = D^1_{\mu_j\bar\mu_j}\left(\underline{R}^{-1}_{\mathrm{W_c}}(V,\Lambda)\right)R_{\mathrm{W_c}}(V,\Lambda)^\mu{}_\nu\epsilon^\nu_{\mu_j}(\boldsymbol{k}_j)\,. \tag{B.31}$$

The relation between $\epsilon^\mu_{\sigma_j}(\boldsymbol{p}_j = \boldsymbol{B}_\mathrm{c}(\boldsymbol{V})k_j)$ and $\epsilon^\mu_{\mu_j}(\boldsymbol{k}_j)$ is then given by

$$\epsilon^\mu_{\mu_j}(\boldsymbol{k}_j)D^1_{\mu_j\sigma_j}\left(\underline{R}^{-1}_{\mathrm{W_c}}(w_j, B_\mathrm{c}(\boldsymbol{V}))\right) = B_\mathrm{c}^{-1}(\boldsymbol{V})^\mu{}_\nu\epsilon^\nu_{\sigma_j}(\boldsymbol{p}_j) \tag{B.32}$$

with $w_j := k_j/m_j$.

B.3.2 Clebsch-Gordan Coefficients

The Clebsch-Gordan coefficient $C^{1\mu_j}_{\frac{1}{2}\tilde\mu_1\frac{1}{2}\tilde\mu_2}$ of Eq. (3.33) can be written in terms of the polarization vectors as [BG79]

$$C^{1\mu_j}_{\frac{1}{2}\tilde\mu_1\frac{1}{2}\tilde\mu_2} = \left(\sigma_\mu\epsilon^\mu_{\mu_j}(\boldsymbol{0})\frac{\mathrm{i}\,\sigma_2}{\sqrt{2}}\right)_{\tilde\mu_1\tilde\mu_2} \tag{B.33}$$

with

$$\sigma_\mu\epsilon^\mu_{\mu_j}(\boldsymbol{0}) = \boldsymbol{\sigma}\cdot\boldsymbol{\epsilon}_{\mu_j}(\boldsymbol{0})\,. \tag{B.34}$$

Explicitly, they are given in matrix form by

$$C^{11}_{\frac{1}{2}\tilde\mu_1\frac{1}{2}\tilde\mu_2} = \delta_{\frac{1}{2}\tilde\mu_1}\delta_{\frac{1}{2}\tilde\mu_2} = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}_{\tilde\mu_1\tilde\mu_2}\,, \tag{B.35}$$

$$C^{1-1}_{\frac{1}{2}\tilde\mu_1\frac{1}{2}\tilde\mu_2} = \delta_{-\frac{1}{2}\tilde\mu_1}\delta_{-\frac{1}{2}\tilde\mu_2} = \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}_{\tilde\mu_1\tilde\mu_2}\,, \tag{B.36}$$

$$C^{10}_{\frac{1}{2}\tilde\mu_1\frac{1}{2}\tilde\mu_2} = \frac{1}{\sqrt{2}}\delta_{\tilde\mu_1-\tilde\mu_2} = \frac{1}{\sqrt{2}}\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}_{\tilde\mu_1\tilde\mu_2}\,. \tag{B.37}$$

Since the Clebsch-Gordan coefficients are real we can write

$$C^{1\mu'_j}_{\frac{1}{2}\tilde\mu'_1\frac{1}{2}\tilde\mu'_2} = C^{1\mu'_j\,*}_{\frac{1}{2}\tilde\mu'_1\frac{1}{2}\tilde\mu'_2} = -\left(\sigma^*_\mu\epsilon^{*\mu}_{\mu'_j}(\boldsymbol{0})\frac{\mathrm{i}\,\sigma^*_2}{\sqrt{2}}\right)_{\tilde\mu'_1\tilde\mu'_2}\,. \tag{B.38}$$

Moreover, due to the symmetry of the Clebsch-Gordan coefficients under $\tilde\mu'_1 \leftrightarrow \tilde\mu'_2$ exchange and the hermiticity of the Pauli matrices we obtain

$$\begin{aligned} C^{1\mu'_j}_{\frac{1}{2}\tilde\mu'_1\frac{1}{2}\tilde\mu'_2} &= C^{1\mu'_j\,\dagger}_{\frac{1}{2}\tilde\mu'_1\frac{1}{2}\tilde\mu'_2} \\ &= -\epsilon^{*\mu}_{\mu'_j}(\boldsymbol{0})\left(\frac{\mathrm{i}\,\sigma_2^\dagger}{\sqrt{2}}\sigma^\dagger_\mu\right)_{\tilde\mu'_2\tilde\mu'_1} \\ &= -\epsilon^{*\mu}_{\mu'_j}(\boldsymbol{0})\left(\frac{\mathrm{i}\,\sigma_2}{\sqrt{2}}\sigma_\mu\right)_{\tilde\mu'_2\tilde\mu'_1}\,. \end{aligned} \tag{B.39}$$

Since the contraction $\sigma_\mu \epsilon^\mu_{\mu_j}(\mathbf{0})$ is Lorentz invariant we can write

$$\begin{aligned}
\sigma_\mu \epsilon^\mu_{\mu_j}(\mathbf{0}) &= \epsilon^\mu_{\mu_j}(\boldsymbol{k}_\mathrm{C}) \mathrm{g}_{\mu\nu} B_\mathrm{c}(\boldsymbol{w}_\mathrm{C})^\nu{}_\rho \sigma^\rho \\
&= \epsilon^\mu_{\mu_j}(\boldsymbol{k}_\mathrm{C}) \mathrm{g}_{\mu\nu} B_\mathrm{c}(\boldsymbol{w}_\mathrm{C})^\nu{}_\rho \mathrm{g}^{\rho\lambda} \sigma_\lambda \\
&= \epsilon^\nu_{\mu_j}(\boldsymbol{k}_\mathrm{C}) B_\mathrm{c}(\boldsymbol{w}_\mathrm{C})_\nu{}^\lambda \sigma_\lambda \\
&= \epsilon^\nu_{\mu_j}(\boldsymbol{k}_\mathrm{C}) B_\mathrm{c}(-\boldsymbol{w}_\mathrm{C})^\lambda{}_\nu \sigma_\lambda \,, \quad w_\mathrm{C} := \frac{k_\mathrm{C}}{m_\mathrm{C}} \,, \qquad \text{(B.40)}
\end{aligned}$$

were we have used Eq. (B.19).

Appendix C

Useful Relations in the SL$(2,\mathbb{C})$ and SU(2)

C.1 Canonical Boosts in the SL$(2,\mathbb{C})$

In Eq. (2.19) a Hermitean SL$(2,\mathbb{C})$-matrix representation of canonical boosts is introduced by

$$\underline{B}_{\mathrm{c}}\,(\boldsymbol{v}) := \sqrt{\frac{v^0+1}{2}}\sigma^0 + \frac{\boldsymbol{\sigma}\cdot\boldsymbol{v}}{\sqrt{2\,(v^0+1)}}\,. \tag{C.1}$$

One can prove by direct calculation that

$$\underline{B}_{\mathrm{c}}\,(\boldsymbol{v})\,\underline{B}_{\mathrm{c}}\,(\boldsymbol{v}) = \sigma^0 v^0 + \sigma_i v^i = \sigma^0 v^0 + \boldsymbol{\sigma}\cdot\boldsymbol{v} = \sigma_\mu v^\mu\,. \tag{C.2}$$

This can be equivalently written as

$$\underline{B}_{\mathrm{c}}\,(\boldsymbol{v})\,\underline{B}_{\mathrm{c}}\,(\boldsymbol{v}) = \underline{B}_{\mathrm{c}}\,(\boldsymbol{v})\,\sigma_\mu(1,\mathbf{0})^\mu\underline{B}_{\mathrm{c}}\,(\boldsymbol{v}) = \sigma_\mu B_{\mathrm{c}}(\boldsymbol{v})^\mu{}_\nu(1,\mathbf{0})^\nu\,. \tag{C.3}$$

Generalizing to arbitrary vectors w gives

$$\underline{B}_{\mathrm{c}}\,(\boldsymbol{v})\,\sigma_\mu w^\mu\underline{B}_{\mathrm{c}}\,(\boldsymbol{v}) = \sigma_\mu B_{\mathrm{c}}(\boldsymbol{v})^\mu{}_\nu w^\nu\,. \tag{C.4}$$

C.2 Useful Relations of Wigner D-Functions

The Wigner D-functions defined by Eq. (2.54) satisfy the following useful relations:

$$\begin{aligned} D^{j*}_{\sigma\sigma'}(\underline{R}) &= D^{j\dagger}_{\sigma'\sigma}(\underline{R}) = D^{j}_{\sigma'\sigma}(\underline{R}^{-1})\,; && \text{(C.5)}\\ \sum_{\sigma''} D^{j}_{\sigma\sigma''}(\underline{R})D^{j}_{\sigma''\sigma'}(\underline{R}') &= D^{j}_{\sigma\sigma'}(\underline{R}\,\underline{R}')\,; && \text{(C.6)}\\ D^{j}_{\sigma\sigma'}(1_2) &= \delta_{\sigma\sigma'}\,; && \text{(C.7)}\\ D^{j}_{\sigma\sigma'}(\underline{R}) &= (-1)^{\sigma'-\sigma}D^{j*}_{-\sigma-\sigma'}(\underline{R})\,. && \text{(C.8)} \end{aligned}$$

For the spin-1/2 case we need the relation

$$
\begin{aligned}
\sigma_2\, D^{\frac{1}{2}*}(\underline{R})\,\sigma_2 &= \begin{pmatrix} D^{\frac{1}{2}*}_{-\frac{1}{2}-\frac{1}{2}}(\underline{R}) & -D^{\frac{1}{2}*}_{-\frac{1}{2}\frac{1}{2}}(\underline{R}) \\ -D^{\frac{1}{2}*}_{\frac{1}{2}-\frac{1}{2}}(\underline{R}) & D^{\frac{1}{2}*}_{\frac{1}{2}\frac{1}{2}}(\underline{R}) \end{pmatrix} \\
&= \begin{pmatrix} D^{\frac{1}{2}}_{\frac{1}{2}\frac{1}{2}}(\underline{R}) & D^{\frac{1}{2}}_{\frac{1}{2}-\frac{1}{2}}(\underline{R}) \\ D^{\frac{1}{2}}_{-\frac{1}{2}\frac{1}{2}}(\underline{R}) & D^{\frac{1}{2}}_{-\frac{1}{2}-\frac{1}{2}}(\underline{R}) \end{pmatrix} \\
&= D^{\frac{1}{2}}(\underline{R})\,, \qquad (C.9)
\end{aligned}
$$

where we have used Eq. (C.8).

C.3 Transformation Properties of the Clebsch-Gordan Coefficients

In order to find the transformation properties of the Clebsch Gordan coefficients under Lorentz transformations (for $l = 0$ bound states) we look at the transformed wave function of Eq. (3.32):

$$
\begin{aligned}
&\Psi_{nj\bar{\mu}_j\bar{\mu}'_1\bar{\mu}'_2}(\bar{\tilde{\boldsymbol{k}}}') \\
&\quad= \Psi_{nj\mu_j\mu'_1\mu'_2}(\tilde{\boldsymbol{k}}')D^{j_1}_{\bar{\mu}'_1\mu'_1}\left[\underline{R}_{\mathrm{W_c}}(V,\mathit{\Lambda})\right] D^{j_2}_{\bar{\mu}'_2\mu'_2}\left[\underline{R}_{\mathrm{W_c}}(V,\mathit{\Lambda})\right] D^{j*}_{\bar{\mu}_j\mu_j}\left[\underline{R}_{\mathrm{W_c}}(V,\mathit{\Lambda})\right] \\
&\quad= C^{j\mu_j}_{j_1\tilde{\mu}_1 j_2\tilde{\mu}_2} u_{n0}(\tilde{k}')D^{j*}_{\bar{\mu}_j\mu_j}\left[\underline{R}_{\mathrm{W_c}}(V,\mathit{\Lambda})\right] \\
&\qquad\times D^{j_1}_{\mu'_1\tilde{\mu}_1}\left[\underline{R}_{\mathrm{W_c}}\left(\tilde{w}'_1, B_{\mathrm{c}}(\boldsymbol{w}'_{12})\right)\right] D^{j_2}_{\mu'_2\tilde{\mu}_2}\left[\underline{R}_{\mathrm{W_c}}\left(\tilde{w}'_2, B_{\mathrm{c}}(\boldsymbol{w}'_{12})\right)\right] \\
&\qquad\times D^{j_1}_{\bar{\mu}'_1\mu'_1}\left[\underline{R}_{\mathrm{W_c}}(V,\mathit{\Lambda})\right] D^{j_2}_{\bar{\mu}'_2\mu'_2}\left[\underline{R}_{\mathrm{W_c}}(V,\mathit{\Lambda})\right]\,. \qquad (C.10)
\end{aligned}
$$

Here we have inserted Eq. (3.15) for the wave function $\Psi_{nj\mu_j\mu'_1\mu'_2}(\tilde{\boldsymbol{k}}')$. On the other hand, from Eq. (3.15), we have

$$
\begin{aligned}
&\Psi_{nj\bar{\mu}_j\bar{\mu}'_1\bar{\mu}'_2}(\bar{\tilde{\boldsymbol{k}}}') \\
&\quad= C^{j\bar{\mu}_j}_{j_1\bar{\tilde{\mu}}_1 j_2\bar{\tilde{\mu}}_2} u_{n0}(\tilde{k}') \\
&\qquad\times D^{j_1}_{\bar{\mu}'_1\bar{\tilde{\mu}}_1}\left[\underline{R}_{\mathrm{W_c}}\left(R_{\mathrm{W_c}}(V,\mathit{\Lambda})\tilde{w}'_1, B_{\mathrm{c}}(\boldsymbol{R}_{\mathrm{W_c}}(V,\mathit{\Lambda})w'_{12})\right)\right] \\
&\qquad\times D^{j_2}_{\bar{\mu}'_2\bar{\tilde{\mu}}_2}\left[\underline{R}_{\mathrm{W_c}}\left(R_{\mathrm{W_c}}(V,\mathit{\Lambda})\tilde{w}'_2, B_{\mathrm{c}}(\boldsymbol{R}_{\mathrm{W_c}}(V,\mathit{\Lambda})w'_{12})\right)\right]\,. \qquad (C.11)
\end{aligned}
$$

Here, we can further simplify the argument of the Wigner D-functions containing the transformed spins (using the short-hand notation $R_{\mathrm{W_c}} := R_{\mathrm{W_c}}(V, \mathit{\Lambda})$):

$$
\begin{aligned}
&\underline{R}_{\mathrm{W_c}}\,(R_{\mathrm{W_c}}\tilde{w}'_1, B_{\mathrm{c}}(\boldsymbol{R}_{\mathrm{W_c}} w'_{12}))\\
&\quad= \underline{B}_{\mathrm{c}}^{-1}(\boldsymbol{B}_{\mathrm{c}}(R_{\mathrm{W_c}} w'_{12}) R_{\mathrm{W_c}}\tilde{w}'_1)\,\underline{B}_{\mathrm{c}}(\boldsymbol{R}_{\mathrm{W_c}} w'_{12})\,\underline{B}_{\mathrm{c}}(\boldsymbol{R}_{\mathrm{W_c}}\tilde{w}'_1)\\
&\quad= \underline{R}_{\mathrm{W_c}}(\tilde{w}'_1, \underbrace{B_{\mathrm{c}}(\boldsymbol{R}_{\mathrm{W_c}} w'_{12}) R_{\mathrm{W_c}}}_{= R_{\mathrm{W_c}} B_{\mathrm{c}}(\boldsymbol{w}'_{12})})\,\underline{B}_{\mathrm{c}}^{-1}(\tilde{\boldsymbol{w}}'_1)\,\underline{R}_{\mathrm{W_c}}^{-1}\\
&\qquad\times \underline{B}_{\mathrm{c}}^{-1}(\boldsymbol{R}_{\mathrm{W_c}} w'_{12})\,\underline{B}_{\mathrm{c}}(\boldsymbol{R}_{\mathrm{W_c}} w'_{12})\,\underline{B}_{\mathrm{c}}(\boldsymbol{R}_{\mathrm{W_c}}\tilde{w}'_1)\\
&\quad= \underline{R}_{\mathrm{W_c}}(\tilde{w}'_1, R_{\mathrm{W_c}} B_{\mathrm{c}}(\boldsymbol{w}'_{12}))\,\underline{B}_{\mathrm{c}}^{-1}(\tilde{\boldsymbol{w}}'_1)\,\underline{R}_{\mathrm{W_c}}^{-1}\,\underline{B}_{\mathrm{c}}(\boldsymbol{R}_{\mathrm{W_c}}\tilde{w}'_1)\\
&\quad= \underline{B}_{\mathrm{c}}^{-1}(\boldsymbol{R}_{\mathrm{W_c}} B_{\mathrm{c}}(\boldsymbol{w}'_{12})\tilde{w}'_1)\,\underline{R}_{\mathrm{W_c}}\,\underline{B}_{\mathrm{c}}(\boldsymbol{w}'_{12})\,\underline{B}_{\mathrm{c}}(\tilde{\boldsymbol{w}}'_1)\,\underline{B}_{\mathrm{c}}^{-1}(\tilde{\boldsymbol{w}}'_1)\,\underline{R}_{\mathrm{W_c}}^{-1}\\
&\qquad\times \underline{R}_{\mathrm{W_c}}\,\underline{B}_{\mathrm{c}}(\tilde{\boldsymbol{w}}'_1)\,\underline{R}_{\mathrm{W_c}}^{-1}\\
&\quad= \underline{R}_{\mathrm{W_c}}\,\underline{B}_{\mathrm{c}}^{-1}(\boldsymbol{B}_{\mathrm{c}}(\boldsymbol{w}'_{12})\tilde{w}'_1)\,\underline{R}_{\mathrm{W_c}}^{-1}\,\underline{R}_{\mathrm{W_c}}\,\underline{B}_{\mathrm{c}}(\boldsymbol{w}'_{12})\,\underline{B}_{\mathrm{c}}(\tilde{\boldsymbol{w}}'_1)\,\underline{R}_{\mathrm{W_c}}^{-1}\\
&\quad= \underline{R}_{\mathrm{W_c}}\,\underline{B}_{\mathrm{c}}^{-1}(\boldsymbol{B}_{\mathrm{c}}(\boldsymbol{w}'_{12})\tilde{w}'_1)\,\underline{B}_{\mathrm{c}}(\boldsymbol{w}'_{12})\,\underline{B}_{\mathrm{c}}(\tilde{\boldsymbol{w}}'_1)\,\underline{R}_{\mathrm{W_c}}^{-1}\\
&\quad= \underline{R}_{\mathrm{W_c}}\,\underline{R}_{\mathrm{W_c}}(\tilde{w}'_1, B_{\mathrm{c}}(\boldsymbol{w}'_{12}))\,\underline{R}_{\mathrm{W_c}}^{-1}\,.
\end{aligned}
\tag{C.12}
$$

Here we have made use of the property of canonical Wigner rotations, Eq. (2.44). A similar calculation applies to constituent 2. Consequently, we can split the Wigner D-functions in Eq. (C.11) into 3 D-functions:

$$
\begin{aligned}
&D^{j_1}_{\bar{\mu}'_1 \bar{\tilde{\mu}}'_1}\left[\underline{R}_{\mathrm{W_c}}\,(R_{\mathrm{W_c}}(V, \mathit{\Lambda})\tilde{w}'_1, B_{\mathrm{c}}(\boldsymbol{R}_{\mathrm{W_c}}(V, \mathit{\Lambda}) w'_{12}))\right]\\
&\qquad= D^{j_1}_{\bar{\mu}'_1 \mu'_1}[\underline{R}_{\mathrm{W_c}}(V, \mathit{\Lambda})] D^{j_1}_{\mu'_1 \tilde{\mu}_1}[\underline{R}_{\mathrm{W_c}}(\tilde{w}'_1, B_{\mathrm{c}}(\boldsymbol{w}'_{12}))] D^{j_1}_{\tilde{\mu}_1 \bar{\tilde{\mu}}_1}[\underline{R}_{\mathrm{W_c}}^{-1}(V, \mathit{\Lambda})]
\end{aligned}
\tag{C.13}
$$

and similarly for constituent 2. Comparing Eqs. (C.10) and (C.11) gives the desired transformation properties of the Clebsch-Gordan coefficients under Lorentz transformations:

$$
\begin{aligned}
&C^{j\mu_j}_{j_1 \tilde{\mu}_1 j_2 \tilde{\mu}_2} \overset{\mathit{\Lambda}}{\to} C^{j\bar{\mu}_j}_{j_1 \bar{\tilde{\mu}}_1 j_2 \bar{\tilde{\mu}}_2}\\
&\qquad= C^{j\mu_j}_{j_1 \tilde{\mu}_1 j_2 \tilde{\mu}_2} D^{j*}_{\bar{\mu}_j \mu_j}\left[\underline{R}_{\mathrm{W_c}}(V, \mathit{\Lambda})\right] D^{j_1}_{\bar{\tilde{\mu}}_1 \tilde{\mu}_1}[\underline{R}_{\mathrm{W_c}}(V, \mathit{\Lambda})] D^{j_2}_{\bar{\tilde{\mu}}_2 \tilde{\mu}_2}[\underline{R}_{\mathrm{W_c}}(V, \mathit{\Lambda})]\,.
\end{aligned}
\tag{C.14}
$$

Appendix D

Electromagnetic Vertices

In this chapter we derive the phenomenological currents from matrix elements of the interaction Lagrangean density and investigate their covariance properties. We also take a closer look at the covariance and continuity properties of the microscopic bound-state current.

D.1 Vertex Interaction

In this section we present the explicit calculation of Eq. (3.72). In the present work we consider two kinds of bound systems: charged mesons (π^+ and ρ^+) consisting of a quark and an antiquark of different flavors (u and $\bar{\mathrm{d}}$) and a charged nucleus (deuteron) consisting of 2 nucleons (proton and neutron). It should be noted that the creation and annihilation operators associated with quark and anti-quark of different flavors anti-commute. In this section we will derive the constituent currents for the point-like case of quarks and then generalize the result to non-pointlike constituents like nucleons.

We start with the left-hand side of Eq. (3.72) and insert for the interaction Lagrangean density Eq. (3.65) at $x = 0$, where constituent 1 is a quark and constituent 2 is an antiquark:

$$
\begin{aligned}
&-\langle \boldsymbol{k}'_{\mathrm{e}}, \mu'_{\mathrm{e}}; \boldsymbol{k}'_1, \mu'_1; \boldsymbol{k}'_2, \mu'_2; \boldsymbol{k}'_\gamma, \mu'_\gamma | \hat{\mathcal{L}}_{\mathrm{int}}(0) | \boldsymbol{k}_{\mathrm{e}}, \mu_{\mathrm{e}}; \boldsymbol{k}_1, \mu_1; \boldsymbol{k}_2, \mu_2 \rangle \\
&\quad = \quad |\,\mathrm{e}\,|\, \langle \boldsymbol{k}'_{\mathrm{e}}, \mu'_{\mathrm{e}}; \boldsymbol{k}'_1, \mu'_1; \boldsymbol{k}'_2, \mu'_2; \boldsymbol{k}'_\gamma, \mu'_\gamma | \Big[Q_{\mathrm{e}} : \hat{\bar{\psi}}_{\mathrm{e}}(0) \gamma^\mu \hat{\psi}_{\mathrm{e}}(0) \hat{A}_\mu(0) : \\
&\qquad\quad + Q_1 : \hat{\bar{\psi}}_1(0) \gamma^\mu \hat{\psi}_1(0) \hat{A}_\mu(0) : + Q_2 : \hat{\bar{\psi}}_2(0) \gamma^\mu \hat{\psi}_2(0) \hat{A}_\mu(0) : \Big] \\
&\qquad \times | \boldsymbol{k}_{\mathrm{e}}, \mu_{\mathrm{e}}; \boldsymbol{k}_1, \mu_1; \boldsymbol{k}_2, \mu_2 \rangle \,.
\end{aligned}
\tag{D.1}
$$

First we concentrate on the second term of this expression:

$$
\begin{aligned}
&\langle \boldsymbol{k}'_{\mathrm{e}}, \mu'_{\mathrm{e}}; \boldsymbol{k}'_1, \mu'_1; \boldsymbol{k}'_2, \mu'_2; \boldsymbol{k}'_\gamma, \mu'_\gamma | : \hat{\bar{\psi}}_1(0)\gamma^\mu \hat{\psi}_1(0)\hat{A}_\mu(0) : | \boldsymbol{k}_{\mathrm{e}}, \mu_{\mathrm{e}}; \boldsymbol{k}_1, \mu_1; \boldsymbol{k}_2, \mu_2 \rangle \\
= \quad & \frac{1}{(2\pi)^3}\int \frac{\mathrm{d}^3 p_1}{2p_1^0} \sum_{\sigma_1=\pm\frac{1}{2}} \frac{1}{(2\pi)^3}\int \frac{\mathrm{d}^3 p'_1}{2p_1'^0} \sum_{\sigma'_1=\pm\frac{1}{2}} \frac{1}{(2\pi)^3}\int \frac{\mathrm{d}^3 p_\gamma}{2|\boldsymbol{p}_\gamma|} \sum_{\lambda_\gamma=0}^{3} (-\mathrm{g}^{\lambda_\gamma\lambda_\gamma}) \\
& \times \bar{u}_{\sigma_1}(\boldsymbol{p}_1)\gamma_\nu u_{\sigma'_1}(\boldsymbol{p}'_1) B_{\mathrm{h}}(\boldsymbol{p})^\nu{}_{\lambda_\gamma} \langle 0 | c_{\mu'_{\mathrm{e}}}(\boldsymbol{k}'_{\mathrm{e}}) d_{\mu'_2}(\boldsymbol{k}'_2) c_{\mu'_1}(\boldsymbol{k}'_1) a_{\mu'_\gamma}(\boldsymbol{k}'_\gamma) \\
& \quad \times : \hat{c}^\dagger_{\sigma_1}(\boldsymbol{p}_1)\hat{c}_{\sigma'_1}(\boldsymbol{p}'_1)\hat{a}^\dagger_{\lambda_\gamma}(\boldsymbol{p}_\gamma) : d^\dagger_{\mu_2}(\boldsymbol{k}_2) c^\dagger_{\mu_{\mathrm{e}}}(\boldsymbol{k}_{\mathrm{e}}) c^\dagger_{\mu_1}(\boldsymbol{k}_1) | 0 \rangle \\
= \quad & \frac{1}{(2\pi)^3}\int \frac{\mathrm{d}^3 p_1}{2p_1^0} \sum_{\sigma_1=\pm\frac{1}{2}} \frac{1}{(2\pi)^3}\int \frac{\mathrm{d}^3 p'_1}{2p_1'^0} \sum_{\sigma'_1=\pm\frac{1}{2}} \frac{1}{(2\pi)^3}\int \frac{\mathrm{d}^3 p_\gamma}{2|\boldsymbol{p}_\gamma|} \sum_{\lambda_\gamma=0}^{3} (-\mathrm{g}^{\lambda_\gamma\lambda_\gamma}) \\
& \times \bar{u}_{\sigma_1}(\boldsymbol{p}_1)\gamma_\nu u_{\sigma'_1}(\boldsymbol{p}'_1) B_{\mathrm{h}}(\boldsymbol{p})^\nu{}_{\lambda_\gamma} \\
& \times \langle 0 | c_{\mu'_1}(\boldsymbol{k}'_1) \hat{c}^\dagger_{\sigma_1}(\boldsymbol{p}_1) | 0 \rangle \langle 0 | \hat{c}_{\sigma'_1}(\boldsymbol{p}'_1) c^\dagger_{\mu_1}(\boldsymbol{k}_1) | 0 \rangle \langle 0 | d_{\mu'_2}(\boldsymbol{k}'_2) d^\dagger_{\mu_2}(\boldsymbol{k}_2) | 0 \rangle \\
& \times \langle 0 | c_{\mu'_{\mathrm{e}}}(\boldsymbol{k}'_{\mathrm{e}}) c^\dagger_{\mu_{\mathrm{e}}}(\boldsymbol{k}_{\mathrm{e}}) | 0 \rangle \langle 0 | a_{\mu'_\gamma}(\boldsymbol{k}'_\gamma) \hat{a}^\dagger_{\lambda_\gamma}(\boldsymbol{p}_\gamma) | 0 \rangle \\
= \quad & \frac{1}{(2\pi)^3}\int \frac{\mathrm{d}^3 p_1}{2p_1^0} \sum_{\sigma_1=\pm\frac{1}{2}} \frac{1}{(2\pi)^3}\int \frac{\mathrm{d}^3 p'_1}{2p_1'^0} \sum_{\sigma'_1=\pm\frac{1}{2}} \frac{1}{(2\pi)^3}\int \frac{\mathrm{d}^3 p_\gamma}{2|\boldsymbol{p}_\gamma|} \sum_{\lambda_\gamma=0}^{3} (-\mathrm{g}^{\lambda_\gamma\lambda_\gamma}) \\
& \times \bar{u}_{\sigma_1}(\boldsymbol{p}_1)\gamma_\nu u_{\sigma'_1}(\boldsymbol{p}'_1) B_{\mathrm{h}}(\boldsymbol{p})^\nu{}_{\lambda_\gamma} (2\pi)^3 \delta_{\sigma_1\mu'_1} 2p_1^0 \delta^3(\boldsymbol{p}_1 - \boldsymbol{k}'_1) \\
& \times (2\pi)^3 \delta_{\sigma'_1\mu_1} 2p_1'^0 \delta^3(\boldsymbol{p}'_1 - \boldsymbol{k}_1) (2\pi)^3 \delta_{\mu_{\mathrm{e}}\mu'_{\mathrm{e}}} 2k_{\mathrm{e}}^0 \delta^3(\boldsymbol{k}'_{\mathrm{e}} - \boldsymbol{k}_{\mathrm{e}}) \\
& \times (2\pi)^3 \delta_{\mu_2\mu'_2} 2k_2^0 \delta^3(\boldsymbol{k}'_2 - \boldsymbol{k}_2) (2\pi)^3 (-\mathrm{g}_{\mu'_\gamma\lambda_\gamma}) 2k_\gamma^0 \delta^3(\boldsymbol{k}'_\gamma - \boldsymbol{p}_\gamma) \\
= \quad & \bar{u}_{\mu'_1}(\boldsymbol{k}'_1)\gamma_\nu u_{\mu_1}(\boldsymbol{k}_1) B_{\mathrm{h}}(\boldsymbol{k}'_\gamma)^\nu{}_{\mu'_\gamma} \\
& \times (2\pi)^3 \delta_{\mu_{\mathrm{e}}\mu'_{\mathrm{e}}} 2k_{\mathrm{e}}^0 \delta^3(\boldsymbol{k}'_{\mathrm{e}} - \boldsymbol{k}_{\mathrm{e}}) (2\pi)^3 \delta_{\mu_2\mu'_2} 2k_2^0 \delta^3(\boldsymbol{k}'_2 - \boldsymbol{k}_2).
\end{aligned}
\tag{D.2}
$$

Here we have used Wick's theorem (see, e.g., Ref. [AH03]), the anti-commutation and commutation relations, Eqs. (3.59) and (3.63), and that the annihilation operators annihilate the vacuum, Eqs. (3.57) and (3.64). The calculation of the first term is equivalent to the one for the second term:

$$
\begin{aligned}
&\langle \boldsymbol{k}'_{\mathrm{e}}, \mu'_{\mathrm{e}}; \boldsymbol{k}'_1, \mu'_1; \boldsymbol{k}'_2, \mu'_2; \boldsymbol{k}'_\gamma, \mu'_\gamma | : \hat{\bar{\psi}}_{\mathrm{e}}(0)\gamma^\mu \hat{\psi}_{\mathrm{e}}(0)\hat{A}_\mu(0) : | \boldsymbol{k}_{\mathrm{e}}, \mu_{\mathrm{e}}; \boldsymbol{k}_1, \mu_1; \boldsymbol{k}_2, \mu_2 \rangle \\
&\quad = \bar{u}_{\mu'_{\mathrm{e}}}(\boldsymbol{k}'_{\mathrm{e}})\gamma_\nu u_{\mu_{\mathrm{e}}}(\boldsymbol{k}_{\mathrm{e}}) B_{\mathrm{h}}(\boldsymbol{k}'_\gamma)^\nu{}_{\mu'_\gamma} \\
&\qquad \times (2\pi)^3 \delta_{\mu_1\mu'_1} 2k_1^0 \delta^3(\boldsymbol{k}'_1 - \boldsymbol{k}_1) (2\pi)^3 \delta_{\mu_2\mu'_2} 2k_2^0 \delta^3(\boldsymbol{k}'_2 - \boldsymbol{k}_2)\,.
\end{aligned}
\tag{D.3}
$$

For the third term we obtain a similar result, except for a relative minus sign which emerges from the normal ordering of the anti-particle operators, $:\hat{d}_{\sigma_1}(\boldsymbol{p}_1)\hat{d}^\dagger_{\sigma'_1}(\boldsymbol{p}'_1) := -\hat{d}^\dagger_{\sigma'_1}(\boldsymbol{p}'_1)\hat{d}_{\sigma_1}(\boldsymbol{p}_1)$, i.e.

$$
\begin{aligned}
&\langle \boldsymbol{k}'_{\mathrm{e}}, \mu'_{\mathrm{e}}; \boldsymbol{k}'_1, \mu'_1; \boldsymbol{k}'_2, \mu'_2; \boldsymbol{k}'_\gamma, \mu'_\gamma | : \hat{\bar{\psi}}_2(0)\gamma^\mu \hat{\psi}_2(0)\hat{A}_\mu(0) : | \boldsymbol{k}_{\mathrm{e}}, \mu_{\mathrm{e}}; \boldsymbol{k}_1, \mu_1; \boldsymbol{k}_2, \mu_2 \rangle \\
&\quad = -\bar{v}_{\mu_2}(\boldsymbol{k}_1)\gamma_\nu v_{\mu'_2}(\boldsymbol{k}'_2) B_{\mathrm{h}}(\boldsymbol{k}'_\gamma)^\nu{}_{\mu'_\gamma} \\
&\qquad \times (2\pi)^3 \delta_{\mu_{\mathrm{e}}\mu'_{\mathrm{e}}} 2k_{\mathrm{e}}^0 \delta^3(\boldsymbol{k}'_{\mathrm{e}} - \boldsymbol{k}_{\mathrm{e}}) (2\pi)^3 \delta_{\mu_1\mu'_1} 2k_2^0 \delta^3(\boldsymbol{k}'_1 - \boldsymbol{k}_1)\,.
\end{aligned}
\tag{D.4}
$$

The matrix elements of the Lagrangean density derived above for point-like spin-$\frac{1}{2}$ particles can be immediately generalized to current matrix elements for extended objects, such as nucleons, mesons or the deuteron. This is done by simply replacing $|\,\mathrm{e}\,|\,Q_i \bar{u}_{\mu_i'}(\boldsymbol{k}_i')\gamma^\mu u_{\mu_i}(\boldsymbol{k}_i)$ by the appropriate expression for the current matrix elements of an extended particle, $J_i^\mu(\boldsymbol{k}_i',\mu_i';\boldsymbol{k}_i,\mu_i)$ and $J_{\mathrm{C}}^\mu(\boldsymbol{k}_{\mathrm{C}}',\mu_j';\boldsymbol{k}_{\mathrm{C}},\mu_j;K_{\mathrm{e}})$.

D.2 Covariance Properties

D.2.1 Phenomenological Currents

In this section we prove the correct transformation properties of the currents $J_i^\mu(\boldsymbol{p}_i',\sigma_i';\boldsymbol{p}_i,\sigma_i)$ defined by Eq. (3.83). Note that the currents $J_i^\mu(\boldsymbol{p}_i',\sigma_i';\boldsymbol{p}_i,\sigma_i)$ are defined via the center-of-momentum currents $J_i^\mu(\boldsymbol{k}_i',\mu_i';\boldsymbol{k}_i,\mu_i)$ whose transformation properties are given by Eq. (3.82). We start our analysis by looking at the Lorentz transformed current:

$$\begin{array}{rl}
\multicolumn{2}{l}{J_i^\mu(\boldsymbol{p}_i',\sigma_i';\boldsymbol{p}_i,\sigma_i) \xrightarrow{\Lambda} J_i^\mu(\boldsymbol{\Lambda p}_i',\bar{\sigma}_i';\boldsymbol{\Lambda}p_i,\bar{\sigma}_i)} \\
= & B_{\mathrm{c}}(\boldsymbol{\Lambda}V)^\mu{}_\nu J_i^\nu(\boldsymbol{R}_{\mathrm{W_c}}(V,\Lambda)k_i',\bar{\mu}_i';\boldsymbol{R}_{\mathrm{W_c}}(V,\Lambda)k_i,\bar{\mu}_i) \\
 & \times D^{j_i*}_{\bar{\mu}_i'\bar{\sigma}_i'}\left[\underline{R}^{-1}_{\mathrm{W_c}}(R_{\mathrm{W_c}}(V,\Lambda)w_i',B_{\mathrm{c}}(\boldsymbol{\Lambda}V))\right] D^{j_i}_{\bar{\mu}_i\bar{\sigma}_i}\left[\underline{R}^{-1}_{\mathrm{W_c}}(R_{\mathrm{W_c}}(V,\Lambda)w_i,B_{\mathrm{c}}(\boldsymbol{\Lambda}V))\right] \\
= & \underbrace{B_{\mathrm{c}}(\boldsymbol{\Lambda}V)^\mu{}_\nu R_{\mathrm{W_c}}(V,\Lambda)^\nu{}_\rho}_{=(\Lambda B_{\mathrm{c}}(\boldsymbol{V}))^\mu{}_\rho} J_i^\rho(\boldsymbol{k}_i',\mu_i';\boldsymbol{k}_i,\mu_i) \\
 & \times D^{j_i*}_{\mu_i'\bar{\mu}_i'}\left[\underline{R}^{-1}_{\mathrm{W_c}}(V,\Lambda)\right] D^{j_i}_{\mu_i\bar{\mu}_i}\left[\underline{R}^{-1}_{\mathrm{W_c}}(V,\Lambda)\right] \\
 & \times D^{j_i*}_{\bar{\mu}_i'\bar{\sigma}_i'}\left[\underline{R}^{-1}_{\mathrm{W_c}}(R_{\mathrm{W_c}}(V,\Lambda)w_i',B_{\mathrm{c}}(\boldsymbol{\Lambda}V))\right] \\
 & \times D^{j_i}_{\bar{\mu}_i\bar{\sigma}_i}\left[\underline{R}^{-1}_{\mathrm{W_c}}(R_{\mathrm{W_c}}(V,\Lambda)w_i,B_{\mathrm{c}}(\boldsymbol{\Lambda}V))\right] \\
= & \Lambda^\mu{}_\nu J_i^\nu(\boldsymbol{p}_i',\sigma_i';\boldsymbol{p}_i,\sigma_i) D^{j_i*}_{\sigma_i'\mu_i'}\left[\underline{R}_{\mathrm{W_c}}(w_i',B_{\mathrm{c}}(\boldsymbol{V}))\right] D^{j_i}_{\sigma_i\mu_i}\left[\underline{R}_{\mathrm{W_c}}(w_i,B_{\mathrm{c}}(\boldsymbol{V}))\right] \\
 & \times D^{j_i*}_{\mu_i'\bar{\sigma}_i'}\left[\underline{R}^{-1}_{\mathrm{W_c}}(V,\Lambda)\underline{R}^{-1}_{\mathrm{W_c}}(R_{\mathrm{W_c}}(V,\Lambda)w_i',B_{\mathrm{c}}(\boldsymbol{\Lambda}V))\right] \\
 & \times D^{j_i}_{\mu_i\bar{\sigma}_i}\left[\underline{R}^{-1}_{\mathrm{W_c}}(V,\Lambda)\underline{R}^{-1}_{\mathrm{W_c}}(R_{\mathrm{W_c}}(V,\Lambda)w_i,B_{\mathrm{c}}(\boldsymbol{\Lambda}V))\right] \\
= & \Lambda^\mu{}_\nu J_i^\nu(\boldsymbol{p}_i',\sigma_i';\boldsymbol{p}_i,\sigma_i) \\
 & \times D^{j_i*}_{\sigma_i'\bar{\sigma}_i'}\left[\underline{R}_{\mathrm{W_c}}(w_i',B_{\mathrm{c}}(\boldsymbol{V}))\underline{R}^{-1}_{\mathrm{W_c}}(V,\Lambda)\underline{R}^{-1}_{\mathrm{W_c}}(R_{\mathrm{W_c}}(V,\Lambda)w_i',B_{\mathrm{c}}(\boldsymbol{\Lambda}V))\right] \\
 & \times D^{j_i}_{\sigma_i\bar{\sigma}_i}\left[\underline{R}_{\mathrm{W_c}}(w_i,B_{\mathrm{c}}(\boldsymbol{V}))\underline{R}^{-1}_{\mathrm{W_c}}(V,\Lambda)\underline{R}^{-1}_{\mathrm{W_c}}(R_{\mathrm{W_c}}(V,\Lambda)w_i,B_{\mathrm{c}}(\boldsymbol{\Lambda}V))\right] \\
= & \Lambda^\mu{}_\nu J_i^\nu(\boldsymbol{p}_i',\sigma_i';\boldsymbol{p}_i,\sigma_i) D^{j_i*}_{\sigma_i'\bar{\sigma}_i'}\left[\underline{R}^{-1}_{\mathrm{W_c}}(v_i',\Lambda)\right] D^{j_i}_{\sigma_i\bar{\sigma}_i}\left[\underline{R}^{-1}_{\mathrm{W_c}}(v_i,\Lambda)\right]\,.
\end{array} \tag{D.5}$$

Here we have used in the last step

$$\begin{array}{rl}
\multicolumn{2}{l}{\underline{R}_{\mathrm{W_c}}(w_i,B_{\mathrm{c}}(\boldsymbol{V}))\underline{R}^{-1}_{\mathrm{W_c}}(V,\Lambda)\underline{R}^{-1}_{\mathrm{W_c}}(R_{\mathrm{W_c}}(V,\Lambda)w_i,B_{\mathrm{c}}(\boldsymbol{\Lambda}V))} \\
= & \underline{B}_{\mathrm{c}}^{-1}(\boldsymbol{v}_i)\underline{B}_{\mathrm{c}}(\boldsymbol{V})\underbrace{\underline{B}_{\mathrm{c}}(\boldsymbol{w}_i)\underline{B}_{\mathrm{c}}^{-1}(\boldsymbol{V})\underline{\Lambda}^{-1}\underline{B}_{\mathrm{c}}(\boldsymbol{\Lambda}V)\underline{B}_{\mathrm{c}}^{-1}(\boldsymbol{R}_{\mathrm{W_c}}(V,\Lambda)w_i)}_{=\underline{R}^{-1}_{\mathrm{W_c}}[w_i,R_{\mathrm{W_c}}(V,\Lambda)]=\underline{R}^{-1}_{\mathrm{W_c}}(V,\Lambda),\ \text{cf. Eq. (2.44)}} \\
 & \times\underline{B}_{\mathrm{c}}^{-1}(\boldsymbol{\Lambda}V)\underline{B}_{\mathrm{c}}(\boldsymbol{B}_{\mathrm{c}}^{-1}(\boldsymbol{\Lambda}V)R_{\mathrm{W_c}}(V,\Lambda)w_i) \\
= & \underline{B}_{\mathrm{c}}^{-1}(\boldsymbol{v}_i)\underline{B}_{\mathrm{c}}(\boldsymbol{V})\underline{R}^{-1}_{\mathrm{W_c}}(V,\Lambda)\underline{B}_{\mathrm{c}}^{-1}(\boldsymbol{\Lambda}V)\underline{B}_{\mathrm{c}}(\boldsymbol{B}_{\mathrm{c}}^{-1}(\boldsymbol{\Lambda}V)R_{\mathrm{W_c}}(V,\Lambda)w_i) \\
= & \underline{B}_{\mathrm{c}}^{-1}(\boldsymbol{v}_i)\underline{\Lambda}^{-1}\underline{B}_{\mathrm{c}}(\boldsymbol{\Lambda}v_i)
\end{array} \tag{D.6}$$

and a similar relation for the primed momenta. We see, by comparison with Eq. (B.20), that $J_i^\mu(\boldsymbol{p}_i',\sigma_i';\boldsymbol{p}_i,\sigma_i)$ transforms under Lorentz transformations like a contravariant four-vector.

D.2.2 Microscopic Bound-State Current

In this section we prove the transformation properties of the bound-state current, Eq. (4.27), under Lorentz transformations for the case of equal constituent masses and for a pure s-wave ($l = l' = 0$). First we note that, under a Lorentz transformation Λ, the center-of-mass momenta of the electron-bound-state system, $k_{\mathrm{C}}^{(\prime)}$, $k_1^{(\prime)}$ and $k_2^{(\prime)}$, undergo a Wigner rotation $R_{\mathrm{W_c}}(V,\Lambda)$. Consequently, their zero components are not affected by a Lorentz transformation, i.e. $\bar{k}_{\mathrm{C}}^{(\prime)0} = k_{\mathrm{C}}^{(\prime)0}$, $\bar{k}_1^{(\prime)0} = k_1^{(\prime)0}$ and $\bar{k}_2^{(\prime)0} = k_2^{(\prime)0}$. Note that under such a Lorentz transformation also the cluster center-of-mass momenta $\tilde{k}_1$ and $\tilde{k}'_1$ undergo the same Wigner rotation, cf. Eq. (3.31). Therefore, the three-dimensional integration measure as well as quantities involving the magnitude of the cluster center-of-mass three-momenta remain invariant under Lorentz transformations, i.e. $\mathrm{d}^3\bar{\tilde{k}}'_1 = \mathrm{d}^3\tilde{k}'_1$, $\bar{\tilde{\boldsymbol{k}}}_1^{(\prime)2} = \tilde{\boldsymbol{k}}_1^{(\prime)2}$ and $\bar{m}_{12}^{(\prime)} = m_{12}^{(\prime)}$. With these findings at hand we look at the Lorentz transformed current of Eq. (4.19):

$$\begin{aligned}
&J_{\mathrm{C}}^{\mu}(\boldsymbol{R}_{\mathrm{W_c}}(V,\Lambda)k'_{\mathrm{C}},\bar{\mu}'_j;\boldsymbol{R}_{\mathrm{W_c}}(V,\Lambda)k_{\mathrm{C}},\bar{\mu}_j;R_{\mathrm{W_c}}(V,\Lambda)K_{\mathrm{e}})\\
&\quad= \frac{\sqrt{k_{\mathrm{C}}^0 k_{\mathrm{C}}'^0}}{4\pi}\int\frac{\mathrm{d}^3\tilde{k}'_1}{k_1^0}\sqrt{\frac{m_{12}}{m'_{12}}}\sqrt{\frac{k_{12}^0}{k_{12}'^0}}u_{n0}^{*}(\tilde{k}')u_{n0}(\tilde{k})\\
&\qquad\times D^{\frac{1}{2}}_{\bar{\bar{\mu}}'_1\bar{\mu}'_1}\left[\underline{R}_{\mathrm{W_c}}^{-1}\left(R_{\mathrm{W_c}}(V,\Lambda)\tilde{w}'_1,B_{\mathrm{c}}(\boldsymbol{R}_{\mathrm{W_c}}(V,\Lambda)w'_{12})\right)\right]C^{j\bar{\mu}'_j\,*}_{\frac{1}{2}\bar{\bar{\mu}}'_1\,\frac{1}{2}\bar{\bar{\mu}}'_2}\\
&\qquad\times D^{\frac{1}{2}}_{\bar{\bar{\mu}}'_2\bar{\bar{\mu}}_2}\left[\underline{R}_{\mathrm{W_c}}\left(R_{\mathrm{W_c}}(V,\Lambda)\tilde{w}_2,B_{\mathrm{c}}^{-1}(\boldsymbol{R}_{\mathrm{W_c}}(V,\Lambda)w'_{12})B_{\mathrm{c}}(\boldsymbol{R}_{\mathrm{W_c}}(V,\Lambda)w_{12})\right)\right]\\
&\qquad\times C^{j\bar{\mu}_j}_{\frac{1}{2}\bar{\bar{\mu}}_1\,\frac{1}{2}\bar{\bar{\mu}}_2}D^{\frac{1}{2}}_{\bar{\mu}_1\bar{\bar{\mu}}_1}\left[\underline{R}_{\mathrm{W_c}}\left(R_{\mathrm{W_c}}(V,\Lambda)\tilde{w}_1,B_{\mathrm{c}}(\boldsymbol{R}_{\mathrm{W_c}}(V,\Lambda)w_{12})\right)\right]\\
&\qquad\times|\,\mathrm{e}\,|\,\bar{u}_{\bar{\mu}'_1}(\boldsymbol{R}_{\mathrm{W_c}}(V,\Lambda)k'_1)(\Gamma_1+\Gamma_2)^{\mu}u_{\bar{\mu}_1}(\boldsymbol{R}_{\mathrm{W_c}}(V,\Lambda)k_1)\,.
\end{aligned}\tag{D.7}$$

Next we look at the product of the two Clebsch-Gordan coefficients between the three Wigner D-functions. Using the transformation properties of the Clebsch-Gordans derived previously, cf. Eq. (3.33), together with Eq. (C.12), which allows to split the transformed D-function into the product of three D-functions, we obtain the following equation:

$$\begin{aligned}
&D^{\frac{1}{2}}_{\bar{\bar{\mu}}'_1\bar{\mu}'_1}\left[\underline{R}_{\mathrm{W_c}}^{-1}\left(R_{\mathrm{W_c}}\tilde{w}'_1,B_{\mathrm{c}}(\boldsymbol{R}_{\mathrm{W_c}}w'_{12})\right)\right]C^{j\bar{\mu}'_j\,*}_{\frac{1}{2}\bar{\bar{\mu}}'_1\,\frac{1}{2}\bar{\bar{\mu}}'_2}\\
&\times D^{\frac{1}{2}}_{\bar{\bar{\mu}}'_2\bar{\bar{\mu}}_2}\left[\underline{R}_{\mathrm{W_c}}\left(R_{\mathrm{W_c}}\tilde{w}_2,B_{\mathrm{c}}^{-1}(\boldsymbol{R}_{\mathrm{W_c}}w'_{12})B_{\mathrm{c}}(\boldsymbol{R}_{\mathrm{W_c}}w_{12})\right)\right]\\
&\times C^{j\bar{\mu}_j}_{\frac{1}{2}\bar{\bar{\mu}}_1\,\frac{1}{2}\bar{\bar{\mu}}_2}D^{\frac{1}{2}}_{\bar{\mu}_1\bar{\bar{\mu}}_1}\left[\underline{R}_{\mathrm{W_c}}\left(R_{\mathrm{W_c}}\tilde{w}_1,B_{\mathrm{c}}(\boldsymbol{R}_{\mathrm{W_c}}w_{12})\right)\right]\\
&\quad= D^{\frac{1}{2}}_{\tilde{\mu}'_1\mu'_1}\left[\underline{R}_{\mathrm{W_c}}^{-1}\left(\tilde{w}'_1,B_{\mathrm{c}}(\boldsymbol{w}'_{12})\right)\right]C^{j\mu'_j\,*}_{\frac{1}{2}\tilde{\mu}'_1\,\frac{1}{2}\tilde{\mu}'_2}\\
&\qquad\times D^{\frac{1}{2}}_{\tilde{\mu}'_2\tilde{\mu}_2}\left[\underline{R}_{\mathrm{W_c}}\left(\tilde{w}_2,B_{\mathrm{c}}^{-1}(\boldsymbol{w}'_{12})B_{\mathrm{c}}(\boldsymbol{w}_{12})\right)\right]\\
&\qquad\times C^{j\mu_j}_{\frac{1}{2}\tilde{\mu}_1\,\frac{1}{2}\tilde{\mu}_2}D^{\frac{1}{2}}_{\mu_1\tilde{\mu}_1}\left[\underline{R}_{\mathrm{W_c}}\left(\tilde{w}_1,B_{\mathrm{c}}(\boldsymbol{w}_{12})\right)\right]\\
&\qquad\times D^{\frac{1}{2}*}_{\bar{\mu}'_1\mu'_1}(\underline{R}_{\mathrm{W_c}})D^{\frac{1}{2}}_{\bar{\mu}_1\mu_1}(\underline{R}_{\mathrm{W_c}})D^{j*}_{\bar{\mu}_j\mu_j}(\underline{R}_{\mathrm{W_c}})D^{j}_{\bar{\mu}'_j\mu'_j}(\underline{R}_{\mathrm{W_c}})\,.
\end{aligned}\tag{D.8}$$

In this calculation the 4 Wigner D-functions $D^{\frac{1}{2}}_{\tilde{\mu}_1\bar{\bar{\mu}}_1}$, $D^{\frac{1}{2}}_{\tilde{\mu}_2\bar{\bar{\mu}}_2}$, $D^{\frac{1}{2}*}_{\tilde{\mu}'_1\bar{\bar{\mu}}'_1}$ and $D^{\frac{1}{2}*}_{\tilde{\mu}'_2\bar{\bar{\mu}}'_2}$ have been canceled with the corresponding inverse ones from the Clebsch-Gordan coefficients. From the transformation properties of the constituent currents, Eq. (3.82), we get 2 more Wigner D-functions which cancel $D^{\frac{1}{2}}_{\bar{\mu}_1\mu_1}$ and

$D^{\frac{1}{2}*}_{\bar{\mu}'_1\mu'_1}$ in Eq. (D.8). With these findings we finally end up with the transformation properties of the microscopic bound-state current given by Eq. (4.27).

D.3 Current Conservation

D.3.1 Pseudoscalar-Bound-State Current

In this appendix we prove the conservation of the electromagnetic current, Eq. (4.33), for pseudoscalar bound states. For simplicity we restrict our considerations to point-like constituents, like quarks, for which the vertex reads $(\mathit{\Gamma}_1 + \mathit{\Gamma}_2)^\mu = (Q_1 + Q_2)\gamma^\mu$. We start with the right-hand side of Eq. (4.34):

$$\begin{aligned}
&(k'_{\mathrm{C}} - k_{\mathrm{C}})_\mu J^\mu_{\mathrm{PS}}(\boldsymbol{k}'_{\mathrm{C}}, \boldsymbol{k}_{\mathrm{C}}, K_{\mathrm{e}}) \\
&\quad = -(\boldsymbol{k}'_{\mathrm{C}} - \boldsymbol{k}_{\mathrm{C}}) \cdot \boldsymbol{J}_{\mathrm{PS}}(\boldsymbol{k}'_{\mathrm{C}}, \boldsymbol{k}_{\mathrm{C}}, K_{\mathrm{e}}) \\
&\quad = -|\,\mathrm{e}\,|\,(Q_1 + Q_2)\frac{1}{4\pi}\frac{\sqrt{k^0_{\mathrm{C}} k'^0_{\mathrm{C}}}}{2} \int \frac{\mathrm{d}^3\tilde{k}'_1}{k^0_1}\sqrt{\frac{m_{12}}{m'_{12}}}\sqrt{\frac{k^0_{12}}{k'^0_{12}}}\, u^*_{n0}(\tilde{k}') u_{n0}(\tilde{k}) \\
&\qquad \times \sum_{\mu'_1\mu_1} D^{\frac{1}{2}}_{\mu_1\mu'_1}\left[\underline{B}_{\mathrm{c}}\,(\boldsymbol{w}_1)\,\sigma_\tau \begin{pmatrix} w^0_{12} \\ -\boldsymbol{w}_{12} \end{pmatrix}^\tau \underline{w}_2\,\sigma_\nu \begin{pmatrix} w'^0_{12} \\ -\boldsymbol{w}'_{12} \end{pmatrix}^\nu \underline{B}_{\mathrm{c}}\,(\boldsymbol{w}'_1)\right] \\
&\qquad \times \bar{u}_{\mu'_1}(\boldsymbol{k}'_1)(\boldsymbol{k}'_1 - \boldsymbol{k}_1) \cdot \boldsymbol{\gamma} u_{\mu_1}(\boldsymbol{k}_1)\,,
\end{aligned} \tag{D.9}$$

since $k'^0_{\mathrm{C}} = k^0_{\mathrm{C}}$ and $\boldsymbol{q} = \boldsymbol{k}'_{\mathrm{C}} - \boldsymbol{k}_{\mathrm{C}} = \boldsymbol{k}'_1 - \boldsymbol{k}_1 = \boldsymbol{q}_1$. In the following calculation we will suppress the argument of the Wigner D-function for better readability. Let us first concentrate on the contraction of the spatial part of the constituent current with $\boldsymbol{q}_1$. Using the standard representation of Dirac spinors, Eq. (B.8), we obtain after a short calculation

$$\begin{aligned}
&\sum_{\mu'_1\mu_1} \bar{u}_{\mu'_1}(\boldsymbol{k}'_1)(\boldsymbol{k}'_1 - \boldsymbol{k}_1) \cdot \boldsymbol{\gamma}\, u_{\mu_1}(\boldsymbol{k}_1) D^{\frac{1}{2}}_{\mu_1\mu'_1} \\
&\quad = \sqrt{k^0_1 + m}\sqrt{k'^0_1 + m}\sum_{\mu'_1\mu_1}\left[\left(\frac{\boldsymbol{k}'^2_1}{k'^0_1 + m} + \frac{\boldsymbol{k}_1 \cdot \boldsymbol{k}'_1}{k^0_1 + m} - \frac{\boldsymbol{k}^2_1}{k^0_1 + m} - \frac{\boldsymbol{k}_1 \cdot \boldsymbol{k}'_1}{k'^0_1 + m}\right)\delta_{\mu_1\mu'_1}\right. \\
&\qquad \left. + \mathrm{i}\,\boldsymbol{k}'_1 \times \boldsymbol{k}_1 \cdot \varsigma^{\mathrm{T}}_{\mu'_1}\boldsymbol{\sigma}\,\varsigma_{\mu_1}\left(\frac{1}{k^0_1 + m} - \frac{1}{k'^0_1 + m}\right)\right] D^{\frac{1}{2}}_{\mu_1\mu'_1}\,,
\end{aligned} \tag{D.10}$$

where we have used Eq. (B.4). On the right-hand side of Eq. (D.10) the terms between the first round brackets are multiplied by $\delta_{\mu_1\mu'_1}$ and the Wigner D-function. Summation over the spins gives for this product

$$\sum_{\mu'_1\mu_1} \delta_{\mu_1\mu'_1} D^{\frac{1}{2}}_{\mu_1\mu'_1} = \sum_{\mu_1} D^{\frac{1}{2}}_{\mu_1\mu_1} = 2\,\Re(D^{\frac{1}{2}}_{\frac{1}{2}\frac{1}{2}})\,, \tag{D.11}$$

where we have used Eq. (C.8). Let us now concentrate on the first two terms between the first round brackets, $\frac{\boldsymbol{k}'^2_1}{k'^0_1+m} + \frac{\boldsymbol{k}_1\cdot\boldsymbol{k}'_1}{k^0_1+m}$. If we replace all primed by unprimed momenta and vice versa we obtain simply $\frac{\boldsymbol{k}^2_1}{k^0_1+m} + \frac{\boldsymbol{k}'_1\cdot\boldsymbol{k}_1}{k'^0_1+m}$. Further, we observe that this expression has just the opposite sign of the second two terms between the first round brackets. Consequently, if we can show that the remaining expressions under the integral in Eq. (D.9) are symmetric under the interchange of primed and unprimed momenta, these 4 terms between the first round brackets cancel upon integration. To this aim we transform the integration measure in Eq. (D.9) according to Eq. (4.25). Then we obtain for the kinematical factors under the integral of Eq. (D.9) the following equality:

$$\frac{\mathrm{d}^3\tilde{k}_1'}{k_1^0}\sqrt{\frac{m_{12}}{m_{12}'}}\sqrt{\frac{k_{12}^0}{k_{12}'^0}} = \frac{\mathrm{d}^3\tilde{k}_1}{k_1'^0}\sqrt{\frac{m_{12}'}{m_{12}}}\sqrt{\frac{k_{12}'^0}{k_{12}^0}}\,. \tag{D.12}$$

It is evident that this expression is symmetric under the interchange of primed and unprimed momenta. The Wigner D-function in Eq. (4.33) transforms under the interchange of primed and unprimed momenta and spins by complex conjugation:

$$\begin{aligned}
& D^{\frac{1}{2}}_{\mu_1\mu_1'}\left[\underline{R}_{\mathrm{W_c}}\left(\tilde{w}_1, B_{\mathrm{c}}(\boldsymbol{w}_{12})\right)\underline{R}^{-1}_{\mathrm{W_c}}\left(\tilde{w}_2, B_{\mathrm{c}}^{-1}(\boldsymbol{w}_{12}')B_{\mathrm{c}}(\boldsymbol{w}_{12})\right)\underline{R}^{-1}_{\mathrm{W_c}}\left(\tilde{w}_1', B_{\mathrm{c}}(\boldsymbol{w}_{12}')\right)\right] \\
& \xrightarrow{\{k_i,\mu_1\}\leftrightarrow\{k_i',\mu_1'\}} \quad D^{\frac{1}{2}}_{\mu_1'\mu_1}\left[\underline{R}_{\mathrm{W_c}}\left(\tilde{w}_1', B_{\mathrm{c}}(\boldsymbol{w}_{12}')\right)\underline{R}^{-1}_{\mathrm{W_c}}\left(\tilde{w}_2, B_{\mathrm{c}}^{-1}(\boldsymbol{w}_{12})B_{\mathrm{c}}(\boldsymbol{w}_{12}')\right)\right. \\
& \qquad\qquad \left.\times\underline{R}^{-1}_{\mathrm{W_c}}\left(\tilde{w}_1, B_{\mathrm{c}}(\boldsymbol{w}_{12})\right)\right] \\
& = \qquad D^{\frac{1}{2}*}_{\mu_1\mu_1'}\left[\underline{R}_{\mathrm{W_c}}\left(\tilde{w}_1, B_{\mathrm{c}}(\boldsymbol{w}_{12})\right)\underline{R}^{-1}_{\mathrm{W_c}}\left(\tilde{w}_2, B_{\mathrm{c}}^{-1}(\boldsymbol{w}_{12}')B_{\mathrm{c}}(\boldsymbol{w}_{12})\right)\right. \\
& \qquad\qquad \left.\times\underline{R}^{-1}_{\mathrm{W_c}}\left(\tilde{w}_1', B_{\mathrm{c}}(\boldsymbol{w}_{12}')\right)\right]\,.
\end{aligned} \tag{D.13}$$

Further we have

$$\sum_{\mu_1'\mu_1}\delta_{\mu_1\mu_1'}D^{\frac{1}{2}*}_{\mu_1\mu_1'} = 2\,\Re(D^{\frac{1}{2}}_{\frac{1}{2}\frac{1}{2}})\,, \tag{D.14}$$

where we have used Eq. (C.8). Thus, by comparison with Eq. (D.11), we see that this expression is also symmetric under the interchange of primed and unprimed momenta. For real radial wave functions $u_{n0}(\tilde{k})$ the product $u_{n0}^*(\tilde{k}')u_{n0}(\tilde{k})$ is also symmetric under interchange of primed and unprimed momenta. Putting the pieces together we have

$$\begin{aligned}
& \sqrt{k_{\mathrm{C}}^0 k_{\mathrm{C}}'^0}\int\frac{\mathrm{d}^3\tilde{k}_1'}{k_1^0}\sqrt{\frac{m_{12}}{m_{12}'}}\sqrt{\frac{k_{12}^0}{k_{12}'^0}}u_{n0}^*(\tilde{k}')\,u_{n0}(\tilde{k}) \\
& \quad\times\sum_{\mu_1'\mu_1}D^{\frac{1}{2}}_{\mu_1\mu_1'}\delta_{\mu_1\mu_1'}\sqrt{k_1^0+m}\sqrt{k_1'^0+m}\left(\frac{\boldsymbol{k}_1'^2}{k_1'^0+m}+\frac{\boldsymbol{k}_1\cdot\boldsymbol{k}_1'}{k_1^0+m}\right) \\
& = \sqrt{k_{\mathrm{C}}^0 k_{\mathrm{C}}'^0}\int\frac{\mathrm{d}^3\tilde{k}_1}{k_1'^0}\sqrt{\frac{m_{12}'}{m_{12}}}\sqrt{\frac{k_{12}'^0}{k_{12}^0}}u_{n0}^*(\tilde{k})\,u_{n0}(\tilde{k}') \\
& \quad\times\sum_{\mu_1'\mu_1}D^{\frac{1}{2}}_{\mu_1'\mu_1}\delta_{\mu_1\mu_1'}\sqrt{k_1^0+m}\sqrt{k_1'^0+m}\left(\frac{\boldsymbol{k}_1'^2}{k_1'^0+m}+\frac{\boldsymbol{k}_1\cdot\boldsymbol{k}_1'}{k_1^0+m}\right) \\
& = \sqrt{k_{\mathrm{C}}^0 k_{\mathrm{C}}'^0}\int\frac{\mathrm{d}^3\tilde{k}_1'}{k_1^0}\sqrt{\frac{m_{12}}{m_{12}'}}\sqrt{\frac{k_{12}^0}{k_{12}'^0}}u_{n0}^*(\tilde{k}')\,u_{n0}(\tilde{k}) \\
& \quad\times\sum_{\mu_1'\mu_1}D^{\frac{1}{2}}_{\mu_1\mu_1'}\delta_{\mu_1\mu_1'}\sqrt{k_1^0+m}\sqrt{k_1'^0+m}\left(\frac{\boldsymbol{k}_1^2}{k_1^0+m}+\frac{\boldsymbol{k}_1'\cdot\boldsymbol{k}_1}{k_1'^0+m}\right)\,.
\end{aligned} \tag{D.15}$$

Here we have in the last step just renamed the integration variable. The right-hand side of this equation is just the negative of the second 2 terms between the first round brackets in Eq. (D.10). Therefore, the first 2 terms cancel the second two terms between the first round brackets due to the relative minus sign.

Next we consider the first term between the second round brackets in Eq. (D.10), $\frac{1}{k_1^0+m}$, which has just the opposite sign of the second term if all primed and unprimed momenta are interchanged. Therefore, in an similar manner as above, we have to show that all other factors are symmetric under the interchange of primed and unprimed momenta in order that these two terms cancel. To this aim we start with the terms proportional to $\varsigma^{\mathrm{T}}_{\mu_1'}\sigma_3\,\varsigma_{\mu_1}$ in Eq. (D.10). The relevant factors to be considered are

$$(\boldsymbol{k}_1' \times \boldsymbol{k}_1)^3 \sum_{\mu_1'\mu_1} \varsigma^{\mathrm{T}}_{\mu_1}\sigma_3\,\varsigma_{\mu_1'}\,D^{\frac{1}{2}}_{\mu_1'\mu_1}\,. \tag{D.16}$$

Performing the sums over the spins gives

$$\sum_{\mu_1'\mu_1} \varsigma^{\mathrm{T}}_{\mu_1'}\sigma_3\,\varsigma_{\mu_1}\,D^{\frac{1}{2}}_{\mu_1\mu_1'} = 2\,\mathrm{i}\,\Im(D^{\frac{1}{2}}_{\frac{1}{2}\frac{1}{2}})\,. \tag{D.17}$$

Under interchange of all primed and unprimed momenta this expression picks up a minus sign:

$$\sum_{\mu_1'\mu_1} \varsigma^{\mathrm{T}}_{\mu_1}\sigma_3\,\varsigma_{\mu_1'}\,D^{\frac{1}{2}}_{\mu_1'\mu_1} = 2\,\mathrm{i}\,\Im(D^{\frac{1}{2}*}_{\frac{1}{2}\frac{1}{2}}) = -2\,\mathrm{i}\,\Im(D^{\frac{1}{2}}_{\frac{1}{2}\frac{1}{2}})\,. \tag{D.18}$$

Since this expression is multiplied by $(\boldsymbol{k}_1' \times \boldsymbol{k}_1)^3$, the product, Eq. (D.16), is again symmetric under primed-unprimed momenta interchange. Therefore, the two terms proportional to $\varsigma^{\mathrm{T}}_{\mu_1'}\sigma_3\,\varsigma_{\mu_1}$ cancel.

The proof for the $\varsigma^{\mathrm{T}}_{\mu_1'}\sigma_2\,\varsigma_{\mu_1}$-terms is similar. Carrying out the spin sums we get

$$\sum_{\mu_1'\mu_1} \varsigma^{\mathrm{T}}_{\mu_1'}\sigma_2\,\varsigma_{\mu_1}\,D^{\frac{1}{2}}_{\mu_1\mu_1'} = -2\,\mathrm{i}\,\Re(D^{\frac{1}{2}}_{-\frac{1}{2}\frac{1}{2}})\,. \tag{D.19}$$

If we interchange again all primed by unprimed variables we find also a relative minus sign:

$$\sum_{\mu_1'\mu_1} \varsigma^{\mathrm{T}}_{\mu_1}\sigma_2\,\varsigma_{\mu_1'}\,D^{\frac{1}{2}}_{\mu_1'\mu_1} = 2\,\mathrm{i}\,\Re(D^{\frac{1}{2}}_{-\frac{1}{2}\frac{1}{2}})\,. \tag{D.20}$$

Therefore,

$$(\boldsymbol{k}_1' \times \boldsymbol{k}_1)^2 \sum_{\mu_1'\mu_1} \varsigma^{\mathrm{T}}_{\mu_1}\sigma_2\,\varsigma_{\mu_1'}\,D^{\frac{1}{2}}_{\mu_1'\mu_1} \tag{D.21}$$

is symmetric under primed-unprimed momenta interchange and the two terms proportional to $\varsigma^{\mathrm{T}}_{\mu_1'}\sigma_2\,\varsigma_{\mu_1}$ cancel.

Finally we are left with the $\varsigma^{\mathrm{T}}_{\mu_1'}\sigma_1\varsigma_{\mu_1}$-terms:

$$\sum_{\mu_1'\mu_1} \varsigma^{\mathrm{T}}_{\mu_1'}\sigma_1\varsigma_{\mu_1}\,D^{\frac{1}{2}}_{\mu_1\mu_1'} = 2\,\mathrm{i}\,\Im(D^{\frac{1}{2}}_{-\frac{1}{2}\frac{1}{2}})\,. \tag{D.22}$$

Interchanging all primed by unprimed variables we find also a relative minus sign:

$$\sum_{\mu_1'\mu_1} \varsigma^{\mathrm{T}}_{\mu_1}\sigma_1\varsigma_{\mu_1'} D^{\frac{1}{2}}_{\mu_1'\mu_1} = -2\,\mathrm{i}\,\Im(D^{\frac{1}{2}}_{-\frac{1}{2}\frac{1}{2}})\,. \tag{D.23}$$

Therefore, also the product

$$(\boldsymbol{k}_1' \times \boldsymbol{k}_1)^1 \sum_{\mu_1'\mu_1} \varsigma^{\mathrm{T}}_{\mu_1}\sigma_1\varsigma_{\mu_1'} D^{\frac{1}{2}}_{\mu_1'\mu_1} \tag{D.24}$$

is invariant under primed-unprimed interchange and the two terms proportional to $\varsigma^{\mathrm{T}}_{\mu_1'}\sigma_1\varsigma_{\mu_1}$ cancel.

Since all contributions cancel each other upon integration over $\tilde{\boldsymbol{k}}_1$ the conservation of our pseudoscalar-bound-state current is proven.

D.3.2 Vector-Bound-State Current

For the vector-bound-state current, Eq. (4.38), current conservation does, unlike the pseudoscalar case, in general not hold. This statement is expressed by Eq. (4.42) and will be justified numerically later on. As we will see in this section, an analytical proof of current conservation along the lines of the pseudoscalar case does not work, since the product of the 3 Wigner D-functions together with the 2 Clebsch-Gordan coefficients in Eq. (4.28) *cannot* be written as one single Wigner D-function. Therefore, it is not possible to use symmetry arguments for the spin-dependent factors under the interchange of primed and unprimed momenta and spins. To see this it suffices to consider the constituents as point-like particles. For better readability we use the following abbreviation for the product of the 3 Wigner D-functions and the 2 Clebsch-Gordan coefficients:

$$\begin{aligned}\mathcal{S}^{\mu_j'\mu_j}_{\mu_1\mu_1'} \quad := \quad & D^{\frac{1}{2}}_{\tilde{\mu}_1'\mu_1'}\left[\underline{R}^{-1}_{\mathrm{W_c}}\left(\tilde{w}_1', B_{\mathrm{c}}(\boldsymbol{w}_{12}')\right)\right] C^{1'\mu_j'*}_{\frac{1}{2}\tilde{\mu}_1'\frac{1}{2}\tilde{\mu}_2'} \\ & \times D^{\frac{1}{2}}_{\tilde{\mu}_2'\tilde{\mu}_2}\left[\underline{R}_{\mathrm{W_c}}\left(\tilde{w}_2, B_{\mathrm{c}}^{-1}(\boldsymbol{w}_{12}')B_{\mathrm{c}}(\boldsymbol{w}_{12})\right)\right] \\ & \times C^{1\mu_j}_{\frac{1}{2}\tilde{\mu}_1\frac{1}{2}\tilde{\mu}_2} D^{\frac{1}{2}}_{\mu_1\tilde{\mu}_1}\left[\underline{R}_{\mathrm{W_c}}\left(\tilde{w}_1, B_{\mathrm{c}}(\boldsymbol{w}_{12})\right)\right]\,.\end{aligned} \tag{D.25}$$

On the right-hand side of Eq. (4.42) we have the contraction of the spatial part of the (point-like) constituent current with $\boldsymbol{q}_1$ (cf. Eq. (4.26))

$$\begin{aligned}&\sum_{\mu_1'\mu_1} \bar{u}_{\mu_1'}(\boldsymbol{k}_1')(\boldsymbol{k}_1' - \boldsymbol{k}_1)\cdot\boldsymbol{\gamma}\,u_{\mu_1}(\boldsymbol{k}_1)\,\mathcal{S}^{\mu_j'\mu_j}_{\mu_1\mu_1'} \\ &\quad = \sqrt{k_1^0 + m}\sqrt{k_1'^0 + m}\sum_{\mu_1'\mu_1}\left[\left(\frac{\boldsymbol{k}_1'^2}{k_1'^0 + m} + \frac{\boldsymbol{k}_1\cdot\boldsymbol{k}_1'}{k_1^0 + m} - \frac{\boldsymbol{k}_1^2}{k_1^0 + m} - \frac{\boldsymbol{k}_1\cdot\boldsymbol{k}_1'}{k_1'^0 + m}\right)\delta_{\mu_1\mu_1'}\right. \\ &\qquad \left. + \mathrm{i}\,\boldsymbol{k}_1' \times \boldsymbol{k}_1 \cdot \varsigma^{\mathrm{T}}_{\mu_1'}\boldsymbol{\sigma}\,\varsigma_{\mu_1}\left(\frac{1}{k_1^0 + m} - \frac{1}{k_1'^0 + m}\right)\right]\mathcal{S}^{\mu_j'\mu_j}_{\mu_1\mu_1'}\,.\end{aligned} \tag{D.26}$$

For the first term proportional to $\delta_{\mu_1\mu_1'}$ we can perform the spin sum

$$\sum_{\mu_1'\mu_1}\delta_{\mu_1\mu_1'}\mathcal{S}^{\mu_j'\mu_j}_{\mu_1\mu_1'} = \sum_{\mu_1}\mathcal{S}^{\mu_j'\mu_j}_{\mu_1\mu_1}\,. \tag{D.27}$$

The important observation is that this expression is, in general, complex and not just a real number like in the pseudoscalar case. On the other hand, by interchanging all primed and unprimed momenta and spins in $\mathcal{S}^{\mu_j'\mu_j}_{\mu_1\mu_1'}$ that are integrated and summed over, respectively, we find

$$\begin{aligned}
\mathcal{S}^{\mu_j'\mu_j}_{\mu_1'\mu_1} &= D^{\frac{1}{2}}_{\tilde{\mu}_1\mu_1}\left[\underline{R}^{-1}_{\mathrm{W_c}}\left(\tilde{w}_1, B_{\mathrm{c}}(\boldsymbol{w}_{12})\right)\right] C^{1\mu_j'*}_{\frac{1}{2}\tilde{\mu}_1\frac{1}{2}\tilde{\mu}_2} \\
&\quad \times D^{\frac{1}{2}}_{\tilde{\mu}_2\tilde{\mu}_2'}\left[\underline{R}_{\mathrm{W_c}}\left(\tilde{w}_2', B_{\mathrm{c}}^{-1}(\boldsymbol{w}_{12})B_{\mathrm{c}}(\boldsymbol{w}_{12}')\right)\right] \\
&\quad \times C^{1\mu_j}_{\frac{1}{2}\tilde{\mu}_1'\frac{1}{2}\tilde{\mu}_2'} D^{\frac{1}{2}}_{\mu_1'\tilde{\mu}_1'}\left[\underline{R}_{\mathrm{W_c}}\left(\tilde{w}_1', B_{\mathrm{c}}(\boldsymbol{w}_{12}')\right)\right] \\
&= \mathcal{S}^{\mu_j'\mu_j *}_{\mu_1\mu_1'}\,.
\end{aligned} \tag{D.28}$$

Carrying out the spin sum of this expression gives

$$\sum_{\mu_1'\mu_1}\delta_{\mu_1\mu_1'}\mathcal{S}^{\mu_j'\mu_j *}_{\mu_1\mu_1'} = \sum_{\mu_1}\mathcal{S}^{\mu_j'\mu_j *}_{\mu_1\mu_1} \neq \sum_{\mu_1}\mathcal{S}^{\mu_j'\mu_j}_{\mu_1\mu_1}\,, \tag{D.29}$$

since this is, in general, a complex number. Consequently, cancellation of the 4 terms between the first round brackets of Eq. (D.26) cannot be shown by simply renaming primed and unprimed momenta and spins that are integrated and summed over.

With a similar argumentation we proceed for the other terms between the second round brackets of Eq. (D.26). For the term proportional to $\varsigma^{\mathrm{T}}_{\mu_1'}\sigma_3\,\varsigma_{\mu_1}$ we can perform the spin sums:

$$\sum_{\mu_1'\mu_1}\varsigma^{\mathrm{T}}_{\mu_1'}\sigma_3\,\varsigma_{\mu_1}\mathcal{S}^{\mu_j'\mu_j}_{\mu_1\mu_1'} = \mathcal{S}^{\mu_j'\mu_j}_{\frac{1}{2}\frac{1}{2}} - \mathcal{S}^{\mu_j'\mu_j}_{-\frac{1}{2}-\frac{1}{2}}\,. \tag{D.30}$$

On the other hand, interchanging all primed and unprimed variables that are summed and integrated over we get

$$\sum_{\mu_1'\mu_1}\varsigma^{\mathrm{T}}_{\mu_1}\sigma_3\,\varsigma_{\mu_1'}\mathcal{S}^{\mu_j'\mu_j *}_{\mu_1\mu_1'} = (\mathcal{S}^{\mu_j'\mu_j}_{\frac{1}{2}\frac{1}{2}} - \mathcal{S}^{\mu_j'\mu_j}_{-\frac{1}{2}-\frac{1}{2}})^*\,. \tag{D.31}$$

Since $\mathcal{S}^{\mu_j'\mu_j}_{\frac{1}{2}\frac{1}{2}} - \mathcal{S}^{\mu_j'\mu_j}_{-\frac{1}{2}-\frac{1}{2}}$ is a complex number, we have in general

$$\mathcal{S}^{\mu_j'\mu_j}_{\frac{1}{2}\frac{1}{2}} - \mathcal{S}^{\mu_j'\mu_j}_{-\frac{1}{2}-\frac{1}{2}} \neq -(\mathcal{S}^{\mu_j'\mu_j}_{\frac{1}{2}\frac{1}{2}} - \mathcal{S}^{\mu_j'\mu_j}_{-\frac{1}{2}-\frac{1}{2}})^* \tag{D.32}$$

and therefore the terms between the round brackets do not cancel.

Similarly, we proceed for the $\varsigma^{\mathrm{T}}_{\mu_1'}\sigma_2\,\varsigma_{\mu_1}$-term:

$$\sum_{\mu_1'\mu_1}\varsigma^{\mathrm{T}}_{\mu_1'}\sigma_2\,\varsigma_{\mu_1}\mathcal{S}^{\mu_j'\mu_j}_{\mu_1\mu_1'} = \mathrm{i}\,(\mathcal{S}^{\mu_j'\mu_j}_{\frac{1}{2}-\frac{1}{2}} - \mathcal{S}^{\mu_j'\mu_j}_{-\frac{1}{2}\frac{1}{2}})\,. \tag{D.33}$$

Interchanging all primed and unprimed variables that are summed and integrated over gives

$$\sum_{\mu_1'\mu_1}\varsigma^{T}_{\mu_1}\sigma_2\,\varsigma_{\mu_1'}\mathcal{S}^{\mu_j'\mu_j *}_{\mu_1\mu_1'} = \mathrm{i}\,(\mathcal{S}^{\mu_j'\mu_j *}_{-\frac{1}{2}\frac{1}{2}} - \mathcal{S}^{\mu_j'\mu_j *}_{\frac{1}{2}-\frac{1}{2}})\,. \tag{D.34}$$

Since, in general

$$(\mathcal{S}^{\mu_j'\mu_j}_{-\frac{1}{2}\frac{1}{2}} - \mathcal{S}^{\mu_j'\mu_j}_{\frac{1}{2}-\frac{1}{2}})^* \neq -(\mathcal{S}^{\mu_j'\mu_j}_{\frac{1}{2}-\frac{1}{2}} - \mathcal{S}^{\mu_j'\mu_j}_{-\frac{1}{2}\frac{1}{2}}) \tag{D.35}$$

the corresponding terms do not cancel.

Finally, for the $\varsigma^{\mathrm{T}}_{\mu_1'}\sigma_1\,\varsigma_{\mu_1}$-term we have

$$\sum_{\mu_1'\mu_1} \varsigma^{\mathrm{T}}_{\mu_1'}\sigma_1\,\varsigma_{\mu_1}\mathcal{S}^{\mu_j'\mu_j}_{\mu_1\mu_1'} = \mathcal{S}^{\mu_j'\mu_j}_{\frac{1}{2}-\frac{1}{2}} + \mathcal{S}^{\mu_j'\mu_j}_{-\frac{1}{2}\frac{1}{2}}\,. \tag{D.36}$$

Interchanging all primed and unprimed variables and summing over gives

$$\sum_{\mu_1'\mu_1} \varsigma^{\mathrm{T}}_{\mu_1}\sigma_1\,\varsigma_{\mu_1'}\mathcal{S}^{\mu_j'\mu_j\,*}_{\mu_1\mu_1'} = \mathcal{S}^{\mu_j'\mu_j\,*}_{-\frac{1}{2}\frac{1}{2}} + \mathcal{S}^{\mu_j'\mu_j\,*}_{\frac{1}{2}-\frac{1}{2}}\,. \tag{D.37}$$

Since, in general

$$(\mathcal{S}^{\mu_j'\mu_j}_{-\frac{1}{2}\frac{1}{2}} + \mathcal{S}^{\mu_j'\mu_j}_{\frac{1}{2}-\frac{1}{2}})^* \neq -(\mathcal{S}^{\mu_j'\mu_j}_{\frac{1}{2}+\frac{1}{2}} - \mathcal{S}^{\mu_j'\mu_j}_{-\frac{1}{2}\frac{1}{2}}) \tag{D.38}$$

the corresponding terms do also not cancel.

Since, in general, the integrals will not vanish by symmetry arguments we do not expect the vector-bound-state current, Eq. (4.38), to be conserved.

D.4 Covariant Structure

The explicit analysis of the covariant structure of the vector bound-state current $J^\mu_{\mathrm{V}}(\boldsymbol{p}_{\mathrm{C}}', \sigma_j'; \boldsymbol{p}_{\mathrm{C}}, \sigma_j; P_{\mathrm{e}})$ is carried out as follows: by multiplying the tensor $\epsilon^{\mu *}_{\sigma_j'}(\boldsymbol{p}_{\mathrm{C}}')\epsilon^{\nu}_{\sigma_j}(\boldsymbol{p}_{\mathrm{C}})$ with the available covariants P^μ_{C}, d^μ and/or P^μ_{e} together with $\mathrm{g}^{\mu\nu}$ we build all independent Hermitean covariants. From the transversality property, Eq. (B.29), follow the relations

$$\epsilon^*_{\sigma_j'}(\boldsymbol{p}_{\mathrm{C}}')\cdot P_{\mathrm{C}} = -\epsilon^*_{\sigma_j'}(\boldsymbol{p}_{\mathrm{C}}')\cdot d \quad \text{and} \quad \epsilon_{\sigma_j}(\boldsymbol{p}_{\mathrm{C}})\cdot P_{\mathrm{C}} = \epsilon_{\sigma_j}(\boldsymbol{p}_{\mathrm{C}})\cdot d\,. \tag{D.39}$$

Then, we can immediately construct the following two independent Hermitean covariants:

$$\epsilon^{\mu *}_{\sigma_j'}(\boldsymbol{p}_{\mathrm{C}}')[\epsilon_{\sigma_j}(\boldsymbol{p}_{\mathrm{C}})\cdot d] - \epsilon^{\mu}_{\sigma_j}(\boldsymbol{p}_{\mathrm{C}})[\epsilon^*_{\sigma_j'}(\boldsymbol{p}_{\mathrm{C}}')\cdot d]\,, \tag{D.40}$$

$$\epsilon^{\mu *}_{\sigma_j'}(\boldsymbol{p}_{\mathrm{C}}')[\epsilon_{\sigma_j}(\boldsymbol{p}_{\mathrm{C}})\cdot P_{\mathrm{e}}] + \epsilon^{\mu}_{\sigma_j}(\boldsymbol{p}_{\mathrm{C}})[\epsilon^*_{\sigma_j'}(\boldsymbol{p}_{\mathrm{C}}')\cdot P_{\mathrm{e}}]\,. \tag{D.41}$$

In order to set up the other covariants we construct all independent scalars where the two polarizations vectors appear either symmetric or antisymmetric under mutual exchange:

$$\begin{gathered}\epsilon^*_{\sigma_j'}(\boldsymbol{p}_{\mathrm{C}}')\cdot\epsilon_{\sigma_j}(\boldsymbol{p}_{\mathrm{C}})\,,\quad [\epsilon^*_{\sigma_j'}(\boldsymbol{p}_{\mathrm{C}}')\cdot d][\epsilon_{\sigma_j}(\boldsymbol{p}_{\mathrm{C}})\cdot d]\,,\quad [\epsilon^*_{\sigma_j'}(\boldsymbol{p}_{\mathrm{C}}')\cdot P_{\mathrm{e}}][\epsilon_{\sigma_j}(\boldsymbol{p}_{\mathrm{C}})\cdot P_{\mathrm{e}}]\,,\\ [\epsilon^*_{\sigma_j'}(\boldsymbol{p}_{\mathrm{C}}')\cdot d][\epsilon_{\sigma_j}(\boldsymbol{p}_{\mathrm{C}})\cdot P_{\mathrm{e}}] \pm [\epsilon^*_{\sigma_j'}(\boldsymbol{p}_{\mathrm{C}}')\cdot P_{\mathrm{e}}][\epsilon_{\sigma_j}(\boldsymbol{p}_{\mathrm{C}})\cdot d]\,.\end{gathered}$$

These scalars are then multiplied with the available covariants P^μ_{C}, d^μ and P^μ_{e}. Now we exclude all anti-Hermitean combinations such that only the following

Hermitean covariants remain:

$$\begin{aligned}
&[\epsilon^*_{\sigma'_j}(\boldsymbol{p}'_{\mathrm{C}})\cdot\epsilon_{\sigma_j}(\boldsymbol{p}_{\mathrm{C}})]P^\mu_{\mathrm{C}}\,, \qquad [\epsilon^*_{\sigma'_j}(\boldsymbol{p}'_{\mathrm{C}})\cdot\epsilon_{\sigma_j}(\boldsymbol{p}_{\mathrm{C}})]P^\mu_{\mathrm{e}}\,,\\
&[\epsilon^*_{\sigma'_j}(\boldsymbol{p}'_{\mathrm{C}})\cdot d][\epsilon_{\sigma_j}(\boldsymbol{p}_{\mathrm{C}})\cdot d]P^\mu_{\mathrm{C}}\,, \qquad [\epsilon^*_{\sigma'_j}(\boldsymbol{p}'_{\mathrm{C}})\cdot d][\epsilon_{\sigma_j}(\boldsymbol{p}_{\mathrm{C}})\cdot d]P^\mu_{\mathrm{e}}\,,\\
&[\epsilon^*_{\sigma'_j}(\boldsymbol{p}'_{\mathrm{C}})\cdot P_{\mathrm{e}}][\epsilon_{\sigma_j}(\boldsymbol{p}_{\mathrm{C}})\cdot P_{\mathrm{e}}]P^\mu_{\mathrm{C}}\,, \qquad [\epsilon^*_{\sigma'_j}(\boldsymbol{p}'_{\mathrm{C}})\cdot P_{\mathrm{e}}][\epsilon_{\sigma_j}(\boldsymbol{p}_{\mathrm{C}})\cdot P_{\mathrm{e}}]P^\mu_{\mathrm{e}}\,,\\
&\{[\epsilon^*_{\sigma'_j}(\boldsymbol{p}'_{\mathrm{C}})\cdot d][\epsilon_{\sigma_j}(\boldsymbol{p}_{\mathrm{C}})\cdot P_{\mathrm{e}}]-[\epsilon^*_{\sigma'_j}(\boldsymbol{p}'_{\mathrm{C}})\cdot P_{\mathrm{e}}][\epsilon_{\sigma_j}(\boldsymbol{p}_{\mathrm{C}})\cdot d]\}P^\mu_{\mathrm{C}}\,,\\
&\{[\epsilon^*_{\sigma'_j}(\boldsymbol{p}'_{\mathrm{C}})\cdot d][\epsilon_{\sigma_j}(\boldsymbol{p}_{\mathrm{C}})\cdot P_{\mathrm{e}}]-[\epsilon^*_{\sigma'_j}(\boldsymbol{p}'_{\mathrm{C}})\cdot P_{\mathrm{e}}][\epsilon_{\sigma_j}(\boldsymbol{p}_{\mathrm{C}})\cdot d]\}P^\mu_{\mathrm{e}}\,,\\
&\{[\epsilon^*_{\sigma'_j}(\boldsymbol{p}'_{\mathrm{C}})\cdot d][\epsilon_{\sigma_j}(\boldsymbol{p}_{\mathrm{C}})\cdot P_{\mathrm{e}}]+[\epsilon^*_{\sigma'_j}(\boldsymbol{p}'_{\mathrm{C}})\cdot P_{\mathrm{e}}][\epsilon_{\sigma_j}(\boldsymbol{p}_{\mathrm{C}})\cdot d]\}d^\mu\,. \qquad \text{(D.42)}
\end{aligned}$$

These 9 covariants together with (D.40) and (D.41) are then 11 Hermitean covariants. Consequently, we can parametrize the current $J^\mu_{\mathrm{V}}(\boldsymbol{p}'_{\mathrm{C}},\sigma'_j;\boldsymbol{p}_{\mathrm{C}},\sigma_j;P_{\mathrm{e}})$ in terms of 11 form factors, the 3 physical form factors f_1, f_2 and g_{M} and 8 spurious form factors $b_1,\ldots,b_8$.

Appendix E

Matrix Elements of the Optical Potential

E.1 Constituent-Level Calculation

In this appendix we present the rather lengthy calculation of the on-shell velocity-state matrix elements of the one-photon-exchange optical potential for elastic electron-bound-state scattering. A similar and quite detailed calculation for the case of spinless constituents can be found in Ref. [Fuc07]. In the same manner we start with Eq. (4.12) and insert completeness relations for free and clustered velocity states, Eqs. (2.77) and (3.37), at the appropriate places:

$$\begin{aligned}
&\langle \underline{V}'; \underline{\boldsymbol{k}}'_{\mathrm{e}}, \underline{\mu}'_{\mathrm{e}}; \underline{\boldsymbol{k}}'_{12}, n, j, \mu'_j | \hat{K} \left(\hat{M}_{\mathrm{eC}\gamma} - M \right)^{-1} \hat{K}^\dagger \\
&\qquad \times | \underline{V}; \underline{\boldsymbol{k}}_{\mathrm{e}}, \underline{\mu}_{\mathrm{e}}; \underline{\boldsymbol{k}}_{12}, n, j, \mu_j \rangle \\
&\quad = \langle \underline{V}'; \underline{\boldsymbol{k}}'_{\mathrm{e}}, \underline{\mu}'_{\mathrm{e}}; \underline{\boldsymbol{k}}'_{12}, n, j, \mu'_j | \hat{1}'_{12\mathrm{e}}\, \hat{K}\, \hat{1}'''_{12\mathrm{e}\gamma} \left(\hat{M}_{\mathrm{eC}\gamma} - M \right)^{-1} \hat{1}''_{\mathrm{Ce}\gamma} \\
&\qquad \times \hat{1}''_{12\mathrm{e}\gamma}\, \hat{K}^\dagger\, \hat{1}_{12\mathrm{e}} | \underline{V}; \underline{\boldsymbol{k}}_{\mathrm{e}}, \underline{\mu}_{\mathrm{e}}; \underline{\boldsymbol{k}}_{12}, n, j, \mu_j \rangle
\end{aligned}$$

$$
\begin{aligned}
&= \frac{1}{(2\pi)^{51}} \int \frac{\mathrm{d}^3 V'}{V'^0} \frac{\mathrm{d}^3 k'_\mathrm{e}}{2k'^0_\mathrm{e}} \frac{\mathrm{d}^3 k'_1}{2k'^0_1} \frac{(k'^0_1 + k'^0_2 + k'^0_\mathrm{e})^3}{2k'^0_2} \sum_{\mu'_\mathrm{e}\mu'_1\mu'_2} \\

&\quad \times \langle V''; \boldsymbol{k}''_\mathrm{e}, \mu''_\mathrm{e}; \boldsymbol{k}''_1, \mu''_1; \boldsymbol{k}''_2, \mu''_2; \boldsymbol{k}''_\gamma, \mu''_\gamma | \hat{K}^\dagger | V; \boldsymbol{k}_\mathrm{e}, \mu_\mathrm{e}; \boldsymbol{k}_1, \mu_1; \boldsymbol{k}_2, \mu_2 \rangle \\
&\quad \times \langle V; \boldsymbol{k}_\mathrm{e}, \mu_\mathrm{e}; \boldsymbol{k}_1, \mu_1; \boldsymbol{k}_2, \mu_2 | \, \underline{V}; \underline{\boldsymbol{k}}_\mathrm{e}, \underline{\mu}_\mathrm{e}; \underline{\boldsymbol{k}}_{12}, n, j, \mu_j \rangle \, . \qquad \text{(E.1)}
\end{aligned}
$$

The matrix elements we need to know are typically scalar products between free and clustered velocity states as well as matrix elements of the vertex operators between free velocity states, which have been already derived previously. The former define the bound-state wave functions on the three- and four-body Hilbert spaces, cf. Eqs. (3.23) and (3.35). The latter consist of 3 terms and are defined by Eq. (3.71). Inserting the latter gives altogether 9 terms which are depicted in Figs. E.1 and E.2. There the blobs that connect the c_1 and c_2 lines stand for integrals over wave functions of the incoming and outgoing bound state.

We are interested only in the 4 contributions of Fig. E.1, since the remaining 5 of Fig. E.2 are self-energy contributions in which the photon is emitted and absorbed by the same particle. The latter contribute to the renormalized masses of the electron and the bound state and will therefore be neglected. The first contribution of Fig. E.1, $\Gamma_{e\to 1}$, where the photon is emitted by the electron and

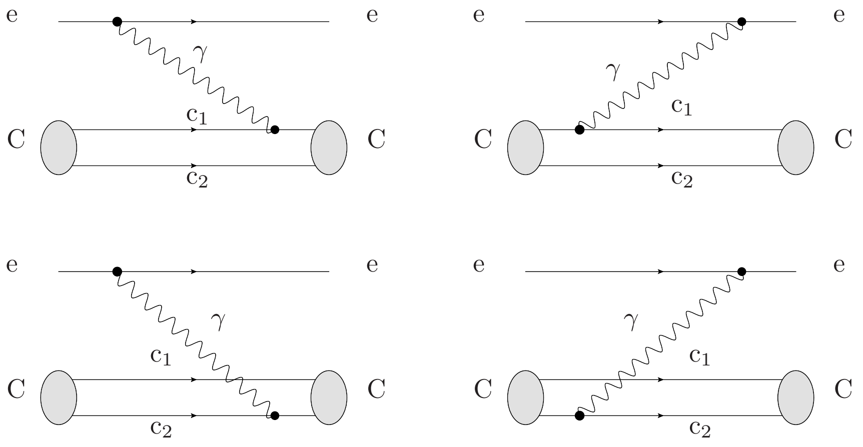

Figure E.1: The graphical representation of the 4 possibilities $\Gamma_{\mathrm{e}\to 1}$, $\Gamma_{1\to\mathrm{e}}$, $\Gamma_{\mathrm{e}\to 2}$ and $\Gamma_{2\to\mathrm{e}}$ to exchange the photon between the electron and one of the constituents.

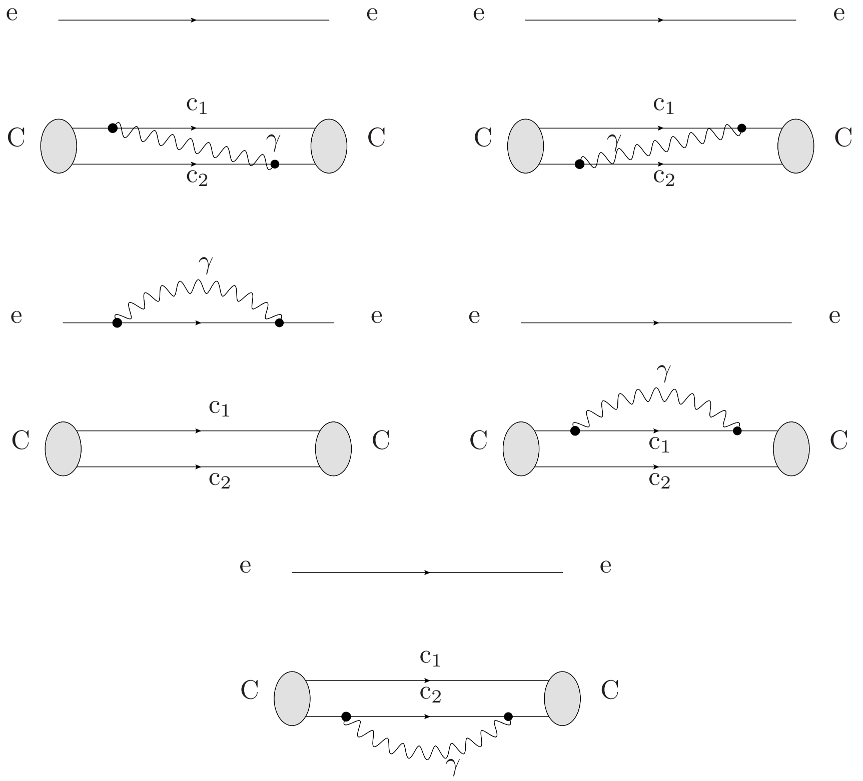

Figure E.2: The graphical representation of the 5 self-energy contributions $\Gamma_{1\to 2}$, $\Gamma_{2\to 1}$, $\Gamma_{\mathrm{e}\to\mathrm{e}}$, $\Gamma_{1\to 1}$ and $\Gamma_{2\to 2}$ to the optical potential, where the photon is emitted and absorbed by the same particle.

absorbed by constituent 1 is given by the rather lengthy expression

$$
\begin{aligned}
\mathit{\Gamma}_{e\rightarrow 1} \quad = \quad & (2\pi)^3 \int \frac{\mathrm{d}^3 V'}{V'^0}\frac{\mathrm{d}^3 k'_\mathrm{e}}{2k'^0_\mathrm{e}}\frac{\mathrm{d}^3 k'_1}{2k'^0_1}\frac{(k'^0_1+k'^0_2+k'^0_\mathrm{e})^3}{2k'^0_2}\sum_{\mu'_\mathrm{e}\mu'_1\mu'_2}\;\sum_{\mu'''_\mathrm{e}\mu'''_1\mu'''_2\mu'''_\gamma}(-\mathrm{g}^{\mu'''_\gamma\mu'''_\gamma}) \\

\end{aligned}
\tag{E.2}
$$

The integrations over $\boldsymbol{V}$, $\boldsymbol{V}'$, $\boldsymbol{V}''$, $\boldsymbol{V}'''$, $\underline{\boldsymbol{V}}''$, $\boldsymbol{k}_\mathrm{e}$, $\boldsymbol{k}'_\mathrm{e}$, $\boldsymbol{k}''_\mathrm{e}$, $\boldsymbol{k}'''_\mathrm{e}$, $\underline{\boldsymbol{k}}''_\mathrm{e}$, $\underline{\boldsymbol{k}}''_\gamma$, $\boldsymbol{k}'''_\gamma$, $\boldsymbol{k}''_1$, $\boldsymbol{k}''_2$, $\boldsymbol{k}'''_2$ together with the sums over μ_e, μ'_e, μ''_e, μ'''_e, $\underline{\mu}''_\mathrm{e}$, μ'''_γ, $\underline{\mu}''_\gamma$, μ''_γ, μ''_1, μ''_2, μ'''_2 can be carried out by means of the corresponding Dirac delta functions and Kronecker deltas, respectively. Then the contribution simplifies to

$$
\begin{aligned}
\mathit{\Gamma}_{e\to 1} \;=\;& (2\pi)^3 \underline{V}^0 \delta^3(\underline{\boldsymbol{V}} - \underline{\boldsymbol{V}}') \\
&\times \int \frac{\mathrm{d}^3 k_1'}{2k_1'^0} \frac{1}{2k_2'^0} \sum_{\mu_1'\mu_2'} \frac{1}{2k_1'''^0} \sum_{\mu_1'''} \frac{1}{2|\boldsymbol{k}_\mathrm{e} - \boldsymbol{k}_\mathrm{e}'|} \sum_{n''j''\mu_j''} \int \frac{\mathrm{d}^3 k_1}{2k_1^0 2k_2^0} \sum_{\mu_1\mu_2} \\
&\times \sqrt{\frac{2\tilde{k}_1'^0 2\tilde{k}_2'^0}{2(\tilde{k}_1'^0 + \tilde{k}_2'^0)}} \sqrt{\frac{2k_{12}'^0 2k_\mathrm{C}'^0}{(k_\mathrm{C}'^0 + \underline{k}_\mathrm{e}'^0)^3}} \mathit{\Psi}^*_{nj\mu_j'\mu_1'\mu_2'}(\tilde{\boldsymbol{k}}') \\
&\times J_{1\nu}(\boldsymbol{k}_1', \mu_1'; \boldsymbol{k}_1''', \mu_1''') \sqrt{\frac{2\tilde{k}_1'''^0 2\tilde{k}_2'''^0}{2(\tilde{k}_1'''^0 + \tilde{k}_2'''^0)}} \sqrt{2k_{12}'''^0} \\
&\times \mathit{\Psi}_{n''j''\mu_j''\mu_1'''\mu_2'}(\tilde{\boldsymbol{k}}''') \left(\underline{k}_\mathrm{e}'^0 + k_\mathrm{C}''^0 + |\boldsymbol{k}_\mathrm{e} - \boldsymbol{k}_\mathrm{e}'| - M\right)^{-1} \\
&\times 2k_{12}^0 \mathit{\Psi}^*_{n''j''\mu_j''\mu_1\mu_2}(\tilde{\boldsymbol{k}})(-\mathrm{g}^{\mu\nu})\,|\,\mathrm{e}\,|\,Q_\mathrm{e}\,\bar{u}_{\underline{\mu}_\mathrm{e}'}(\boldsymbol{k}_\mathrm{e}')\gamma_\mu u_{\underline{\mu}_\mathrm{e}}(\boldsymbol{k}_e) \\
&\times \frac{2\tilde{k}_1^0 2\tilde{k}_2^0}{2(\tilde{k}_1^0 + \tilde{k}_2^0)} \sqrt{\frac{2k_\mathrm{C}^0}{(k_\mathrm{C}^0 + \underline{k}_\mathrm{e}^0)^3}} \mathit{\Psi}_{nj\mu_j\mu_1\mu_2}(\tilde{\boldsymbol{k}})\,. \qquad \text{(E.3)}
\end{aligned}
$$

Here we have used the completeness relation for the photon polarization vectors Eq. (B.23). Furthermore, the delta function $\delta^3(\boldsymbol{k}_2'' - \boldsymbol{k}_2)$ of Eq. (E.2) has been rewritten according to $\delta^3(\boldsymbol{k}_2'' - \boldsymbol{k}_2) = \delta^3(\boldsymbol{k}_\gamma'' - (\boldsymbol{k}_\mathrm{e} - \boldsymbol{k}_\mathrm{e}'))$ by using $\underline{\boldsymbol{k}}_\mathrm{e}' + \underline{\boldsymbol{k}}_\gamma' + \underline{\boldsymbol{k}}_1 = -\underline{\boldsymbol{k}}_2''$ and $\underline{\boldsymbol{k}}_\mathrm{e} + \underline{\boldsymbol{k}}_1 = -\underline{\boldsymbol{k}}_2$. For better readability we have kept $\boldsymbol{k}_1''' = \boldsymbol{k}_1' - \underline{\boldsymbol{k}}_\mathrm{e} + \underline{\boldsymbol{k}}_\mathrm{e}'$ and $\boldsymbol{k}_2''' = \boldsymbol{k}_2'$. In Ref. [Fuc07] the Jacobian for the variable transformation between the integration measures $\mathrm{d}^3 k_1$ and $\mathrm{d}^3 \tilde{k}_1$ has been derived:

$$
\mathrm{d}^3 k_1 = \mathrm{d}^3 \tilde{k}_1 \frac{2k_1^0 2k_2^0}{2\tilde{k}_1^0 2\tilde{k}_2^0} \frac{2(\tilde{k}_1^0 + \tilde{k}_2^0)}{2(k_1^0 + k_2^0)}\,. \qquad \text{(E.4)}
$$

Subsequently, the integration over $\mathrm{d}^3 \tilde{k}_1$ can be carried out with the help of the normalization condition of the wave function, Eq. (3.16). For the special case of a pure central potential as used, e.g., in Ref. [KSK03], the normalization condition can be proved with the help of the appropriate orthogonality relations of the Wigner *D*-functions, the Clebsch-Gordan coefficients and the spherical harmonics, Eqs. (C.7), (2.89) and (2.88):

$$
\begin{aligned}
&\int \mathrm{d}^3 \tilde{k}_1 \sum_{\mu_1\mu_2} \mathit{\Psi}^*_{n''j''\mu_j''(l''s'')\mu_1\mu_2}(\tilde{\boldsymbol{k}}) \mathit{\Psi}_{nj\mu_j(ls)\mu_1\mu_2}(\tilde{\boldsymbol{k}}) \\
&= \int \mathrm{d}^3 \tilde{k}_1 \sum_{\mu_l''\mu_s''\tilde{\mu}_1''\tilde{\mu}_2''\mu_l\mu_s\tilde{\mu}_1\tilde{\mu}_2} Y^*_{l''\mu_l''}(\hat{\tilde{\boldsymbol{k}}}) C^{s''\mu_s''}_{j_1\tilde{\mu}_1''j_2\tilde{\mu}_2''} C^{j''\mu_j''}_{l''\mu_l''s''\mu_s''} u^*_{n''l''}(\tilde{k}) \\
&\quad \times Y_{l\mu_l}(\hat{\tilde{\boldsymbol{k}}}) C^{s\mu_s}_{j_1\tilde{\mu}_1 j_2\tilde{\mu}_2} C^{j\mu_j}_{l\mu_l s\mu_s} u_{nl}(\tilde{k}) \\
&\quad \times \underbrace{\sum_{\mu_1} D^{j_1}_{\tilde{\mu}_1''\mu_1}\left[\underline{R}^{-1}_{\mathrm{W_c}}\left(\tilde{w}_1, B_\mathrm{c}(\boldsymbol{w}_{12})\right)\right] D^{j_1}_{\mu_1\tilde{\mu}_1}\left[\underline{R}_{\mathrm{W_c}}\left(\tilde{w}_1, B_\mathrm{c}(\boldsymbol{w}_{12})\right)\right]}_{=\delta_{\tilde{\mu}_1\tilde{\mu}_1''},\ \text{Eq. (C.7)}} \\
&\quad \times \underbrace{\sum_{\mu_2} D^{j_2}_{\tilde{\mu}_2''\mu_2}\left[\underline{R}^{-1}_{\mathrm{W_c}}\left(\tilde{w}_2, B_\mathrm{c}(\boldsymbol{w}_{12})\right)\right] D^{j_2}_{\mu_2\tilde{\mu}_2}\left[\underline{R}_{\mathrm{W_c}}\left(\tilde{w}_2, B_\mathrm{c}(\boldsymbol{w}_{12})\right)\right]}_{=\delta_{\tilde{\mu}_2\tilde{\mu}_2''},\ \text{Eq. (C.7)}}
\end{aligned}
$$

$$
\begin{aligned}
&= \int \mathrm{d}\tilde{k}\,\tilde{k}^2 \sum_{\mu_l''\mu_s''\mu_l\mu_s} \underbrace{\sum_{\tilde{\mu}_1\tilde{\mu}_2} C^{s''\mu_s''}_{j_1\tilde{\mu}_1 j_2\tilde{\mu}_2} C^{s\mu_s}_{j_1\tilde{\mu}_1 j_2\tilde{\mu}_2}}_{=\delta_{ss''}\delta_{\mu_s\mu_s''}\text{ , Eq. (2.89)}} C^{j''\mu_j''}_{l''\mu_l''s''\mu_s''} u^*_{n''l''}(\tilde{k}) \\
&\quad \times \underbrace{\int \mathrm{d}\Omega(\hat{\tilde{\boldsymbol{k}}}) Y^*_{l''\mu_l''}(\hat{\tilde{\boldsymbol{k}}}) Y_{l\mu_l}(\hat{\tilde{\boldsymbol{k}}})}_{=\delta_{ll''}\delta_{\mu_l\mu_l''}\text{ , Eq. (2.88)}} C^{j\mu_j}_{l\mu_l s\mu_s} u_{nl}(\tilde{k}) \\
&= \sum_{\mu_l\mu_s} C^{j''\mu_j''}_{l\mu_l s\mu_s} C^{j\mu_j}_{l\mu_l s\mu_s} \int \mathrm{d}\tilde{k}\,\tilde{k}^2 u^*_{n''l}(\tilde{k}) u_{nl}(\tilde{k}) \\
&= \delta_{jj''}\delta_{\mu_j\mu_j''}\delta_{nn''}\,. \qquad \text{(E.5)}
\end{aligned}
$$

Here we have assumed that the radial wave functions are normalized to unity:

$$\int \mathrm{d}\tilde{k}\,\tilde{k}^2 u^*_{n''l}(\tilde{k}) u_{nl}(\tilde{k}) = \delta_{nn''}\,. \qquad \text{(E.6)}$$

Finally we denote all incoming momenta and spins by unprimed symbols and all outgoing momenta and spins by primed symbols. Then the result reads

$$
\begin{aligned}
\mathit{\Gamma}_{e\to 1} &= (2\pi)^3 \underline{V}^0 \delta^3(\underline{\boldsymbol{V}} - \underline{\boldsymbol{V}}') \frac{1}{2|\boldsymbol{k}_\mathrm{e} - \boldsymbol{k}_\mathrm{e}'|} \sqrt{\frac{2k_\mathrm{C}'^0}{(k_\mathrm{C}'^0 + \underline{k}_\mathrm{e}'^0)^3}} \sqrt{\frac{2k_\mathrm{C}^0}{(k_\mathrm{C}^0 + \underline{k}_\mathrm{e}^0)^3}} \\
&\quad \times \left(\underline{k}_\mathrm{e}'^0 + k_\mathrm{C}^0 + |\boldsymbol{k}_\mathrm{e} - \boldsymbol{k}_\mathrm{e}'| - M\right)^{-1} \\
&\quad \times \int \frac{\mathrm{d}^3 k_1'}{2k_1'^0} \frac{1}{2k_2'^0} \frac{1}{2k_1^0} \\
&\quad \times \sqrt{2k_{12}'^0} \sqrt{2k_{12}^0} \sqrt{\frac{2\tilde{k}_1'^0 2\tilde{k}_2'^0}{2(\tilde{k}_1'^0 + \tilde{k}_2'^0)}} \sqrt{\frac{2\tilde{k}_1^0 2\tilde{k}_2^0}{2(\tilde{k}_1^0 + \tilde{k}_2^0)}} \\
&\quad \times \sum_{\mu_1\mu_1'\mu_2'} \mathit{\Psi}^*_{nj\mu_j'\mu_1'\mu_2'}(\tilde{\boldsymbol{k}}') \mathit{\Psi}_{nj\mu_j\mu_1\mu_2'}(\tilde{\boldsymbol{k}}) \\
&\quad \times J_{1\nu}(\boldsymbol{k}_1', \mu_1'; \boldsymbol{k}_1, \mu_1)(-\mathrm{g}^{\mu\nu})\,|\,\mathrm{e}\,|\,Q_\mathrm{e}\,\bar{u}_{\underline{\mu}_\mathrm{e}'}(\boldsymbol{k}_\mathrm{e}')\gamma_\mu u_{\underline{\mu}_\mathrm{e}}(\boldsymbol{k}_e)\,. \qquad \text{(E.7)}
\end{aligned}
$$

In this expression the momenta satisfy the relations $\boldsymbol{k}_1 = \boldsymbol{k}_1' - (\boldsymbol{k}_\mathrm{e} - \boldsymbol{k}_\mathrm{e}')$ since $\boldsymbol{k}_2' = \boldsymbol{k}_2 \Rightarrow -\boldsymbol{k}_1' - \underline{\boldsymbol{k}}_\mathrm{e}' = -\boldsymbol{k}_1 - \underline{\boldsymbol{k}}_\mathrm{e}' - \underline{\boldsymbol{k}}_\gamma''$. The other three contributions from Fig. E.1 are obtained in an analogous manner and will not be calculated here explicitly. They read

$$
\begin{aligned}
\mathit{\Gamma}_{e\to 2} &= (2\pi)^3 \underline{V}^0 \delta^3(\underline{\boldsymbol{V}} - \underline{\boldsymbol{V}}') \frac{1}{2|\boldsymbol{k}_\mathrm{e} - \boldsymbol{k}_\mathrm{e}'|} \sqrt{\frac{2k_\mathrm{C}'^0}{(k_\mathrm{C}'^0 + \underline{k}_\mathrm{e}'^0)^3}} \sqrt{\frac{2k_\mathrm{C}^0}{(k_\mathrm{C}^0 + \underline{k}_\mathrm{e}^0)^3}} \\
&\quad \times \left(\underline{k}_\mathrm{e}'^0 + k_\mathrm{C}^0 + |\boldsymbol{k}_\mathrm{e} - \boldsymbol{k}_\mathrm{e}'| - M\right)^{-1} \\
&\quad \times \int \frac{\mathrm{d}^3 k_2'}{2k_1'^0} \frac{1}{2k_2'^0} \frac{1}{2k_2^0} \\
&\quad \times \sqrt{2k_{12}'^0} \sqrt{2k_{12}^0} \sqrt{\frac{2\tilde{k}_1'^0 2\tilde{k}_2'^0}{2(\tilde{k}_1'^0 + \tilde{k}_2'^0)}} \sqrt{\frac{2\tilde{k}_1^0 2\tilde{k}_2^0}{2(\tilde{k}_1^0 + \tilde{k}_2^0)}} \\
&\quad \times \sum_{\mu_2\mu_1'\mu_2'} \mathit{\Psi}^*_{nj\mu_j'\mu_1'\mu_2'}(\tilde{\boldsymbol{k}}') \mathit{\Psi}_{nj\mu_j\mu_1'\mu_2}(\tilde{\boldsymbol{k}}) \\
&\quad \times J_{2\nu}(\boldsymbol{k}_2', \mu_2'; \boldsymbol{k}_2, \mu_2)(-\mathrm{g}^{\mu\nu})\,|\,\mathrm{e}\,|\,Q_\mathrm{e}\,\bar{u}_{\underline{\mu}_\mathrm{e}'}(\boldsymbol{k}_\mathrm{e}')\gamma_\mu u_{\underline{\mu}_\mathrm{e}}(\boldsymbol{k}_e) \qquad \text{(E.8)}
\end{aligned}
$$

where $\boldsymbol{k}_2 = \boldsymbol{k}'_2 - (\boldsymbol{k}_\mathrm{e} - \boldsymbol{k}'_\mathrm{e})$ and $\boldsymbol{k}'_1 = \boldsymbol{k}_1$,

$$\begin{aligned}
\Gamma_{1\to\mathrm{e}} \quad = \quad & (2\pi)^3 \underline{V}^0 \delta^3(\underline{\boldsymbol{V}} - \underline{\boldsymbol{V}}') \frac{1}{2|\boldsymbol{k}'_\mathrm{e} - \boldsymbol{k}_\mathrm{e}|} \sqrt{\frac{2k'^0_\mathrm{C}}{(k'^0_\mathrm{C} + \underline{k}'^0_\mathrm{e})^3}} \sqrt{\frac{2k^0_\mathrm{C}}{(k^0_\mathrm{C} + \underline{k}^0_\mathrm{e})^3}} \\
& \times \left(\underline{k}^0_\mathrm{e} + k'^0_\mathrm{C} + |\boldsymbol{k}'_\mathrm{e} - \boldsymbol{k}_\mathrm{e}| - M\right)^{-1} \\
& \times \int \frac{\mathrm{d}^3 k_1}{2k^0_1} \frac{1}{2k^0_2} \frac{1}{2k'^0_1} \\
& \times \sqrt{2k'^0_{12}} \sqrt{2k^0_{12}} \sqrt{\frac{2\tilde{k}'^0_1 2\tilde{k}'^0_2}{2(\tilde{k}'^0_1 + \tilde{k}'^0_2)}} \sqrt{\frac{2\tilde{k}^0_1 2\tilde{k}^0_2}{2(\tilde{k}^0_1 + \tilde{k}^0_2)}} \\
& \times \sum_{\mu'_1 \mu_1 \mu_2} \Psi^*_{nj\mu'_j \mu'_1 \mu_2}(\tilde{\boldsymbol{k}}') \Psi_{nj\mu_j \mu_1 \mu_2}(\tilde{\boldsymbol{k}}) \\
& \times J_{1\nu}(\boldsymbol{k}'_1, \mu'_1; \boldsymbol{k}_1, \mu_1)(-\mathrm{g}^{\mu\nu}) \,|\,\mathrm{e}\,|\, Q_\mathrm{e}\, \bar{u}_{\underline{\mu}'_\mathrm{e}}(\boldsymbol{k}'_\mathrm{e}) \gamma_\mu u_{\underline{\mu}_\mathrm{e}}(\boldsymbol{k}_e)
\end{aligned} \tag{E.9}$$

where $\boldsymbol{k}'_1 = \boldsymbol{k}_1 - (\boldsymbol{k}'_\mathrm{e} - \boldsymbol{k}_\mathrm{e})$ and $\boldsymbol{k}'_2 = \boldsymbol{k}_2$ and finally

$$\begin{aligned}
\Gamma_{2\to\mathrm{e}} \quad = \quad & (2\pi)^3 \underline{V}^0 \delta^3(\underline{\boldsymbol{V}} - \underline{\boldsymbol{V}}') \frac{1}{2|\boldsymbol{k}'_\mathrm{e} - \boldsymbol{k}_\mathrm{e}|} \sqrt{\frac{2k'^0_\mathrm{C}}{(k'^0_\mathrm{C} + \underline{k}'^0_\mathrm{e})^3}} \sqrt{\frac{2k^0_\mathrm{C}}{(k^0_\mathrm{C} + \underline{k}^0_\mathrm{e})^3}} \\
& \times \left(\underline{k}^0_\mathrm{e} + k'^0_\mathrm{C} + |\boldsymbol{k}'_\mathrm{e} - \boldsymbol{k}_\mathrm{e}| - M\right)^{-1} \\
& \times \int \frac{\mathrm{d}^3 k_2}{2k^0_1} \frac{1}{2k^0_2} \frac{1}{2k'^0_2} \\
& \times \sqrt{2k'^0_{12}} \sqrt{2k^0_{12}} \sqrt{\frac{2\tilde{k}'^0_1 2\tilde{k}'^0_2}{2(\tilde{k}'^0_1 + \tilde{k}'^0_2)}} \sqrt{\frac{2\tilde{k}^0_1 2\tilde{k}^0_2}{2(\tilde{k}^0_1 + \tilde{k}^0_2)}} \\
& \times \sum_{\mu'_2 \mu_1 \mu_2} \Psi^*_{nj\mu'_j \mu_1 \mu'_2}(\tilde{\boldsymbol{k}}') \Psi_{nj\mu_j \mu_1 \mu_2}(\tilde{\boldsymbol{k}}) \\
& \times J_{2\nu}(\boldsymbol{k}'_2, \mu'_2; \boldsymbol{k}_2, \mu_2)(-\mathrm{g}^{\mu\nu}) \,|\,\mathrm{e}\,|\, Q_\mathrm{e}\, \bar{u}_{\underline{\mu}'_\mathrm{e}}(\boldsymbol{k}'_\mathrm{e}) \gamma_\mu u_{\underline{\mu}_\mathrm{e}}(\boldsymbol{k}_e)
\end{aligned} \tag{E.10}$$

where $\boldsymbol{k}'_2 = \boldsymbol{k}_2 - (\boldsymbol{k}'_\mathrm{e} - \boldsymbol{k}_\mathrm{e})$ and $\boldsymbol{k}'_1 = \boldsymbol{k}_1$.

E.2 Combining the Time Orderings

The next step towards a simplification of the sum of the four contributions we have obtained above is to combine the 2 possible time orderings for each exchange process to one covariant contribution. To this end we use for $\Gamma_{1\to\mathrm{e}}$ the spectator condition $k^0_2 = k'^0_2$ and the equality of integration measures $\mathrm{d}^3 k_1 = \mathrm{d}^3 k'_1$ since $\boldsymbol{k}'_\mathrm{e} - \boldsymbol{k}_\mathrm{e}$ is a constant. Moreover, we can simply rename the spin indices that are summed over according to the spectator condition $\mu_2 = \mu'_2$ and by the replacement $\mu_1 \leftrightarrow \mu'_1$. These rewritings make $\Gamma_{1\to\mathrm{e}}$ easier comparable with $\Gamma_{\mathrm{e}\to 1}$. An analogous manipulation applies to $\Gamma_{2\to\mathrm{e}}$. Consequently, after neglecting the self-energy contributions, the optical potential, Eq. (E.1), becomes

$$
\begin{aligned}
&\mathit{\Gamma}_{\mathrm{e}\to 1} + \mathit{\Gamma}_{1\to\mathrm{e}} + \mathit{\Gamma}_{\mathrm{e}\to 2} + \mathit{\Gamma}_{2\to\mathrm{e}} \\
&= \quad (2\pi)^3 \underline{V}^0 \delta^3(\underline{\boldsymbol{V}} - \underline{\boldsymbol{V}}') \frac{1}{2|\boldsymbol{k}_{\mathrm{e}} - \boldsymbol{k}'_{\mathrm{e}}|} \sqrt{\frac{2k'^0_{\mathrm{C}}}{(k'^0_{\mathrm{C}} + \underline{k}'^0_{\mathrm{e}})^3}} \sqrt{\frac{2k^0_{\mathrm{C}}}{(k^0_{\mathrm{C}} + \underline{k}^0_{\mathrm{e}})^3}} \\
&\quad \times \left[\left(\underline{k}'^0_{\mathrm{e}} + k^0_{\mathrm{C}} + |\boldsymbol{k}_{\mathrm{e}} - \boldsymbol{k}'_{\mathrm{e}}| - M \right)^{-1} + \left(\underline{k}^0_{\mathrm{e}} + k'^0_{\mathrm{C}} + |\boldsymbol{k}'_{\mathrm{e}} - \boldsymbol{k}_{\mathrm{e}}| - M \right)^{-1} \right] \\
&\quad \times \sum_{\mu'_1 \mu'_2} \left[\int \frac{\mathrm{d}^3 k'_1}{2k'^0_1} \frac{1}{2k'^0_2} \frac{1}{2k^0_1} \sqrt{\frac{2\tilde{k}'^0_1 2\tilde{k}'^0_2}{2(\tilde{k}'^0_1 + \tilde{k}'^0_2)}} \sqrt{\frac{2\tilde{k}^0_1 2\tilde{k}^0_2}{2(\tilde{k}^0_1 + \tilde{k}^0_2)}} \sqrt{2k'^0_{12}} \sqrt{2k^0_{12}} \right. \\
&\qquad \times \sum_{\mu_1} \mathit{\Psi}^*_{nj\mu'_j \mu'_1 \mu'_2}(\tilde{\boldsymbol{k}}') \mathit{\Psi}_{nj\mu_j \mu_1 \mu'_2}(\tilde{\boldsymbol{k}}) J_{1\nu}(\boldsymbol{k}'_1, \mu'_1; \boldsymbol{k}_1, \mu_1) \\
&\qquad + \int \frac{\mathrm{d}^3 k'_2}{2k'^0_2} \frac{1}{2k'^0_1} \frac{1}{2k^0_2} \sqrt{\frac{2\tilde{k}'^0_1 2\tilde{k}'^0_2}{2(\tilde{k}'^0_1 + \tilde{k}'^0_2)}} \sqrt{\frac{2\tilde{k}^0_1 2\tilde{k}^0_2}{2(\tilde{k}^0_1 + \tilde{k}^0_2)}} \sqrt{2k'^0_{12}} \sqrt{2k^0_{12}} \\
&\qquad \left. \times \sum_{\mu_2} \mathit{\Psi}^*_{nj\mu'_j \mu'_1 \mu'_2}(\tilde{\boldsymbol{k}}') \mathit{\Psi}_{nj\mu_j \mu'_1 \mu_2}(\tilde{\boldsymbol{k}}) J_{2\nu}(\boldsymbol{k}'_2, \mu'_2; \boldsymbol{k}_2, \mu_2) \right] \\
&\quad \times (-\mathrm{g}^{\mu\nu}) \,|\,\mathrm{e}\,|\, Q_{\mathrm{e}} \, \bar{u}_{\underline{\mu}'_{\mathrm{e}}}(\boldsymbol{k}'_{\mathrm{e}}) \gamma_\mu u_{\underline{\mu}_{\mathrm{e}}}(\boldsymbol{k}_e) \, . \qquad \text{(E.11)}
\end{aligned}
$$

The two terms in the first square brackets correspond to the two possible time orderings, i.e. emission of the photon with subsequent absorption by one of the constituents and vice versa. Since we consider on-shell matrix elements, cf. Eq. (4.10), both time orderings of the photon exchange can be combined to give the covariant photon propagator:

$$
\begin{aligned}
&\left(\underline{k}'^0_{\mathrm{e}} + k^0_{\mathrm{C}} + |\boldsymbol{k}_{\mathrm{e}} - \boldsymbol{k}'_{\mathrm{e}}| - M \right)^{-1} + \left(\underline{k}^0_{\mathrm{e}} + k'^0_{\mathrm{C}} + |\boldsymbol{k}'_{\mathrm{e}} - \boldsymbol{k}_{\mathrm{e}}| - M \right)^{-1} \\
&\quad = \frac{2|\boldsymbol{k}'_{\mathrm{e}} - \boldsymbol{k}_{\mathrm{e}}|}{(k^0_{\mathrm{e}} - k'^0_{\mathrm{e}})(k^0_{\mathrm{C}} - k'^0_{\mathrm{C}}) + (\boldsymbol{k}_{\mathrm{e}} - \boldsymbol{k}'_{\mathrm{e}})^2} \\
&\quad = \frac{2|\boldsymbol{k}'_{\mathrm{e}} - \boldsymbol{k}_{\mathrm{e}}|}{Q^2} \, , \qquad \text{(E.12)}
\end{aligned}
$$

with the four-momentum transfer to the bound-state (or equivalently of the electron) given by

$$
q := \begin{pmatrix} k'^0_{\mathrm{C}} - k^0_{\mathrm{C}} \\ \boldsymbol{k}'_{12} - \boldsymbol{k}_{12} \end{pmatrix} \equiv \begin{pmatrix} k^0_{\mathrm{e}} - k'^0_{\mathrm{e}} \\ \boldsymbol{k}_{\mathrm{e}} - \boldsymbol{k}'_{\mathrm{e}} \end{pmatrix} \quad \text{and} \quad Q^2 := -q^\mu q_\mu \, . \qquad \text{(E.13)}
$$

Note that the three-momentum of the photon is $\boldsymbol{k}''_\gamma = \pm(\boldsymbol{k}'_{\mathrm{e}} - \boldsymbol{k}_{\mathrm{e}}) = \pm\boldsymbol{q}$. Here the sign depends on the time ordering whereas $k^{0\prime\prime}_\gamma = |\,(\boldsymbol{k}'_{\mathrm{e}} - \boldsymbol{k}_{\mathrm{e}})| = Q \neq q^0$ is independent of the time ordering. This modification further simplifies Eq. (E.11), which then finally takes the form given by Eq. (4.14).

Appendix F

Extraction of the Electromagnetic Form Factors

F.1 Current Matrix Elements

Similarly as in the pseudoscalar case we extract the electromagnetic form factors of a vector bound state, f_1, f_2 and $g_{\rm M}$, from Eq. (5.9) in the limit $k \to \infty$, where the form factors become independent of k. First we shall analyze the behavior of the current (5.9) in this limit. For better readability we use the following abbreviations for the covariants multiplying the form factors. The covariants associated with the physical form factors f_1, f_2 and $g_{\rm M}$ are defined by

$$
\begin{aligned}
L_1^\mu(\mu_j', \mu_j) \quad &:= \quad \epsilon^*_{\mu_j'}(\boldsymbol{k}'_{\rm C}) \cdot \epsilon_{\mu_j}(\boldsymbol{k}_{\rm C}) K^\mu_{\rm C}\,, && \text{(F.1)}\\
L_2^\mu(\mu_j', \mu_j) \quad &:= \quad \frac{[\epsilon^*_{\mu_j'}(\boldsymbol{k}'_{\rm C}) \cdot q][\epsilon_{\mu_j}(\boldsymbol{k}_{\rm C}) \cdot q]}{2m_{\rm C}^2} K^\mu_{\rm C}\,, && \text{(F.2)}\\
L_{\rm M}^\mu(\mu_j', \mu_j) \quad &:= \quad \left\{\epsilon^{\mu *}_{\mu_j'}(\boldsymbol{k}'_{\rm C})[\epsilon_{\mu_j}(\boldsymbol{k}_{\rm C}) \cdot q] - \epsilon^\mu_{\mu_j}(\boldsymbol{k}_{\rm C})[\epsilon^*_{\mu_j'}(\boldsymbol{k}'_{\rm C}) \cdot q]\right\}\,, && \text{(F.3)}
\end{aligned}
$$

respectively. The K_{e}-dependent spurious covariants which are multiplied with the spurious form factors $b_1, \ldots, b_8$ are denoted by

$$C_1^\mu(\mu_j', \mu_j) := \epsilon^*_{\mu_j'}(\boldsymbol{k}_{\mathrm{C}}') \cdot \epsilon_{\mu_j}(\boldsymbol{k}_{\mathrm{C}}) \frac{m_{\mathrm{C}}^2 K_{\mathrm{e}}^\mu}{K_{\mathrm{e}} \cdot K_{\mathrm{C}}}\,, \tag{F.4}$$

$$C_2^\mu(\mu_j', \mu_j) := [\epsilon^*_{\mu_j'}(\boldsymbol{k}_{\mathrm{C}}') \cdot q][\epsilon_{\mu_j}(\boldsymbol{k}_{\mathrm{C}}) \cdot q] \frac{K_{\mathrm{e}}^\mu}{K_{\mathrm{e}} \cdot K_{\mathrm{C}}}\,, \tag{F.5}$$

$$C_3^\mu(\mu_j', \mu_j) := 4\left\{[\epsilon^*_{\mu_j'}(\boldsymbol{k}_{\mathrm{C}}') \cdot K_{\mathrm{e}}][\epsilon_{\mu_j}(\boldsymbol{k}_{\mathrm{C}}) \cdot K_{\mathrm{e}}]\right\} \frac{m_{\mathrm{C}}^4 K_{\mathrm{e}}^\mu}{(K_{\mathrm{e}} \cdot K_{\mathrm{C}})^3}\,, \tag{F.6}$$

$$C_4^\mu(\mu_j', \mu_j) := \left\{[\epsilon^*_{\mu_j'}(\boldsymbol{k}_{\mathrm{C}}') \cdot q][\epsilon_{\mu_j}(\boldsymbol{k}_{\mathrm{C}}) \cdot K_{\mathrm{e}}] - [\epsilon^*_{\mu_j'}(\boldsymbol{k}_{\mathrm{C}}') \cdot K_{\mathrm{e}}][\epsilon_{\mu_j}(\boldsymbol{k}_{\mathrm{C}}) \cdot q]\right\} \frac{m_{\mathrm{C}}^2 K_{\mathrm{e}}^\mu}{(K_{\mathrm{e}} \cdot K_{\mathrm{C}})^2}\,, \tag{F.7}$$

$$C_5^\mu(\mu_j', \mu_j) := \frac{[\epsilon^*_{\mu_j'}(\boldsymbol{k}_{\mathrm{C}}') \cdot K_{\mathrm{e}}][\epsilon_{\mu_j}(\boldsymbol{k}_{\mathrm{C}}) \cdot K_{\mathrm{e}}]}{(K_{\mathrm{e}} \cdot K_{\mathrm{C}})^2} 4 m_{\mathrm{C}}^2 K_{\mathrm{C}}^\mu\,, \tag{F.8}$$

$$C_6^\mu(\mu_j', \mu_j) := \frac{[\epsilon^*_{\mu_j'}(\boldsymbol{k}_{\mathrm{C}}') \cdot q][\epsilon_{\mu_j}(\boldsymbol{k}_{\mathrm{C}}) \cdot K_{\mathrm{e}}] - [\epsilon^*_{\mu_j'}(\boldsymbol{k}_{\mathrm{C}}') \cdot K_{\mathrm{e}}][\epsilon_{\mu_j}(\boldsymbol{k}_{\mathrm{C}}) \cdot q]}{K_{\mathrm{e}} \cdot K_{\mathrm{C}}} K_{\mathrm{C}}^\mu\,, \tag{F.9}$$

$$C_7^\mu(\mu_j', \mu_j) := 2 m_{\mathrm{C}}^2 \frac{\epsilon^{\mu *}_{\mu_j'}(\boldsymbol{k}_{\mathrm{C}}')[\epsilon_{\mu_j}(\boldsymbol{k}_{\mathrm{C}}) \cdot K_{\mathrm{e}}] + \epsilon^\mu_{\mu_j}(\boldsymbol{k}_{\mathrm{C}})[\epsilon^*_{\mu_j'}(\boldsymbol{k}_{\mathrm{C}}') \cdot K_{\mathrm{e}}]}{K_{\mathrm{e}} \cdot K_{\mathrm{C}}}\,, \tag{F.10}$$

$$C_8^\mu(\mu_j', \mu_j) := \frac{[\epsilon^*_{\mu_j'}(\boldsymbol{k}_{\mathrm{C}}') \cdot q][\epsilon_{\mu_j}(\boldsymbol{k}_{\mathrm{C}}) \cdot K_{\mathrm{e}}] + [\epsilon^*_{\mu_j'}(\boldsymbol{k}_{\mathrm{C}}') \cdot K_{\mathrm{e}}][\epsilon_{\mu_j}(\boldsymbol{k}_{\mathrm{C}}) \cdot q]}{K_{\mathrm{e}} \cdot K_{\mathrm{C}}} q^\mu\,. \tag{F.11}$$

Using our standard kinematics introduced in Sec. 5.3.1 the non-vanishing covariants in the limit $k \to \infty$ are given by

$$L_2^\mu(1,-1) \overset{k\to\infty}{\longrightarrow} -\frac{Q^2}{4 m_{\mathrm{C}}^2} 2k (1,0,0,1)^\mu\,, \tag{F.12}$$

$$L_{\mathrm{M}}^\mu(1,-1) \overset{k\to\infty}{\longrightarrow} -\frac{Q^2}{2 m_{\mathrm{C}}} (1,0,0,1)^\mu\,, \tag{F.13}$$

$$L_1^\mu(1,0) \overset{k\to\infty}{\longrightarrow} \left(-\frac{Q(4(k-m_{\mathrm{C}})m_{\mathrm{C}}+Q^2)}{2\sqrt{2} m_{\mathrm{C}}^2}, 0, 0, -\frac{Q(4(k-m_{\mathrm{C}})m_{\mathrm{C}}+Q^2)}{2\sqrt{2} m_{\mathrm{C}}^2}\right)^\mu\,, \tag{F.14}$$

$$L_2^\mu(1,0) \overset{k\to\infty}{\longrightarrow} \left(\frac{4(k-m_{\mathrm{C}})m_{\mathrm{C}}Q^3+Q^5}{8\sqrt{2} m_{\mathrm{C}}^4}, 0, 0, \frac{4(k-m_{\mathrm{C}})m_{\mathrm{C}}Q^3+Q^5}{8\sqrt{2} m_{\mathrm{C}}^4}\right)^\mu\,, \tag{F.15}$$

$$L_{\mathrm{M}}^\mu(1,0) \overset{k\to\infty}{\longrightarrow} \left(-\frac{Q(2k\, m_{\mathrm{C}}+Q^2)}{2\sqrt{2} m_{\mathrm{C}}^2}, 0, \frac{\mathrm{i}\, Q^2}{2\sqrt{2} m_{\mathrm{C}}}, -\frac{Q(2k\, m_{\mathrm{C}}+Q^2)}{2\sqrt{2} m_{\mathrm{C}}^2}\right)^\mu\,, \tag{F.16}$$

$$C_5^\mu(1,0) \overset{k\to\infty}{\longrightarrow} -\frac{Q}{\sqrt{2}} (1,0,0,1)^\mu\,, \tag{F.17}$$

$$C_6^\mu(1,0) \overset{k\to\infty}{\longrightarrow} \frac{Q(2k\, m_{\mathrm{C}}+Q^2)}{2\sqrt{2} m_{\mathrm{C}}^2} (1,0,0,1)^\mu\,, \tag{F.18}$$

$$C_7^\mu(1,0) \overset{k\to\infty}{\longrightarrow} \frac{1}{\sqrt{2}}(-Q, -m_{\mathrm{C}}, \mathrm{i}\, m_{\mathrm{C}}, -Q)^\mu\,, \tag{F.19}$$

$$C_8^\mu(1,0) \overset{k\to\infty}{\longrightarrow} (0, \frac{Q^2}{2\sqrt{2} m_{\mathrm{C}}}, 0, 0)^\mu\,, \tag{F.20}$$

$$L_1^\mu(1,1) \overset{k\to\infty}{\longrightarrow} -(2k+\frac{Q^2}{m_\mathrm{C}})\,(1,0,0,1)^\mu\ , \tag{F.21}$$

$$L_2^\mu(1,1) \overset{k\to\infty}{\longrightarrow} \frac{2k\,m_\mathrm{C}Q^2+Q^4}{4m_\mathrm{C}^3}\,(1,0,0,1)^\mu\ , \tag{F.22}$$

$$L_\mathrm{M}^\mu(1,1) \overset{k\to\infty}{\longrightarrow} \left(-\frac{Q^2}{2m_\mathrm{C}},0,\mathrm{i}\,Q,-\frac{Q^2}{2m_\mathrm{C}}\right)^\mu\ , \tag{F.23}$$

$$C_6^\mu(1,1) \overset{k\to\infty}{\longrightarrow} \frac{Q^2}{2m_\mathrm{C}}\,(1,0,0,1)^\mu\ , \tag{F.24}$$

$$L_1^\mu(0,0) \overset{k\to\infty}{\longrightarrow} \frac{-2k\,m_\mathrm{C}^2+(k-2m_\mathrm{C})Q^2}{m_\mathrm{C}^2}\,(1,0,0,1)^\mu\ , \tag{F.25}$$

$$L_2^\mu(0,0) \overset{k\to\infty}{\longrightarrow} -\frac{(k-2m_\mathrm{C})Q^4}{4m_\mathrm{C}^4}\,(1,0,0,1)^\mu\ , \tag{F.26}$$

$$L_M^\mu(0,0) \overset{k\to\infty}{\longrightarrow} -\frac{(-k+m_\mathrm{C})Q^2}{m_\mathrm{C}^2}(1,0,0,1)^\nu\,, \tag{F.27}$$

$$C_5^\mu(0,0) \overset{k\to\infty}{\longrightarrow} k\,(2,0,0,2)^\mu\ , \tag{F.28}$$

$$C_6^\mu(0,0) \overset{k\to\infty}{\longrightarrow} \frac{(-k+m_\mathrm{C})Q^2}{2m_\mathrm{C}^2}\,(2,0,0,2)^\mu\ , \tag{F.29}$$

$$C_7^\mu(0,0) \overset{k\to\infty}{\longrightarrow} k(2,0,0,2)^\mu\,. \tag{F.30}$$

It becomes evident that the current is not conserved, not even in the limit $k\to\infty$, due to the non-vanishing contributions of $C_7^1(1,0)$ and $C_8^1(1,0)$ (note that for the given kinematics the four-momentum transfer is $q^\mu=(0,Q,0,0)^\mu$). In addition, we observe, using our kinematics, that the zeroth and third components of the current become identical in this limit, i.e.

$$J^0_{\mu_j'\mu_j} := \lim_{k\to\infty} J^0_\mathrm{V}(\boldsymbol{k}_\mathrm{C}',\mu_j';\boldsymbol{k}_\mathrm{C},\mu_j;K_\mathrm{e}) = \lim_{k\to\infty} J^3_\mathrm{V}(\boldsymbol{k}_\mathrm{C}',\mu_j';\boldsymbol{k}_\mathrm{C},\mu_j;K_\mathrm{e}) = J^3_{\mu_j'\mu_j}\,. \tag{F.31}$$

This reduces the number of independent matrix elements given by (5.37) from 11 to 7. Consequently, we need 7 form factors, the 3 physical f_1, f_2, g_M and the 4 spurious form factors $b_5,\dots,b_8$, to parametrize the current in the limit $k\to\infty$. From Eqs. (F.12)-(F.30) we find the following leading-order contributions to the current matrix elements in the limit $k\to\infty$ (using the short-hand notation

$\lim_{k\to\infty} J^\mu_{\mathrm{V}}(\boldsymbol{k}'_{\mathrm{C}},\mu'_j;\boldsymbol{k}_{\mathrm{C}},\mu_j;K_{\mathrm{e}}) \equiv J^\mu_{\mu'_j\mu_j}$ and $\lim_{k\to\infty} f_i(Q^2,k) \equiv F_i(Q^2)$):

$$\begin{aligned}
\frac{1}{|\,\mathrm{e}\,|}\,J^0_{00} &= F_1L^0_1(0,0)+F_2L^0_2(0,0)+G_{\mathrm{M}}L^0_{\mathrm{M}}(0,0)\\
&\quad +B_6C^0_6(0,0)+B_5C^0_5(0,0)+B_7C^0_7(0,0)+\mathcal{O}(k^0)\,, \qquad \text{(F.32)}\\
\frac{1}{|\,\mathrm{e}\,|}\,J^0_{11} &= F_1L^0_1(1,1)+F_2L^0_2(1,1)+\mathcal{O}(k^0)\,, \qquad \text{(F.33)}\\
\frac{1}{|\,\mathrm{e}\,|}\,J^0_{10} &= F_1L^0_1(1,0)+F_2L^0_2(1,0)+G_{\mathrm{M}}L^0_{\mathrm{M}}(1,0)+B_6C^0_6(1,0)+\mathcal{O}(k^0)\,, \qquad \text{(F.34)}\\
\frac{1}{|\,\mathrm{e}\,|}\,J^0_{1-1} &= F_2L_2(1,-1)+\mathcal{O}(k^0)\,, \qquad \text{(F.35)}\\
\frac{1}{|\,\mathrm{e}\,|}\,J^2_{11} &= G_{\mathrm{M}}L^2_{\mathrm{M}}(1,1)+\mathcal{O}(k^{-1})\,, \qquad \text{(F.36)}\\
\frac{1}{|\,\mathrm{e}\,|}\,J^1_{10} &= B_7C^1_7(1,0)+B_8C^1_8(1,0)+\mathcal{O}(k^{-1})\,, \qquad \text{(F.37)}\\
\frac{1}{|\,\mathrm{e}\,|}\,J^2_{10} &= B_7C^2_7(1,0)+\mathcal{O}(k^{-1})\,. \qquad \text{(F.38)}
\end{aligned}$$

We observe that the current components J^0_{11}, J^0_{1-1} and J^2_{11} do not contain any dominant spurious contributions and are therefore "good" components for the extraction of the physical form factors. With the help of the limiting expressions for the kinematical factors and constituent currents, cf. Eqs. (5.13) and (5.17), respectively, we find for the limit of the zeroth (and third component) of the current (divided by $2k|\,\mathrm{e}\,|$) the following overlap integral:

$$\begin{aligned}
&\frac{1}{|\,\mathrm{e}\,|}\lim_{k\to\infty}\frac{1}{2k}J^0_{\mathrm{V}}(\mu'_j,\mu_j)\\
&\quad = \frac{1}{4\pi}\int \mathrm{d}^3\tilde{k}'_1\sqrt{\frac{m_{12}}{m'_{12}}}u^*_{n0}\left(\tilde{k}'_1\right)u_{n0}\left(\tilde{k}_1\right)\\
&\qquad \times\left\{\left[F^1_1(Q^2)+F^2_1(Q^2)\right]\mathcal{S}^{\mu'_j\mu_j}_1+\sqrt{\tau}\left[F^1_2(Q^2)+F^2_2(Q^2)\right]\mathcal{S}^{\mu'_j\mu_j}_2\right\}\,. \qquad \text{(F.39)}
\end{aligned}$$

Here $\mathcal{S}^{\mu'_j\mu_j}_1$ and $\mathcal{S}^{\mu'_j\mu_j}_2$ are the spin factors from the Wigner D-functions and Clebsch-Gordan coefficients as given by Eqs. (5.51) and (5.52). Then using Eqs. (F.12), (F.21) and (F.22) the physical form factors F_1 and F_2 can be extracted from $J^0_{\mathrm{V}}(1,1)$ and $J^0_{\mathrm{V}}(1,-1)$ according to

$$\begin{aligned}
F_1(Q^2) &:= \lim_{k\to\infty} f_1(Q^2,k) = -\frac{1}{|\,\mathrm{e}\,|}\lim_{k\to\infty}\frac{1}{2k}\left[J^0_{\mathrm{V}}(1,1)+J^0_{\mathrm{V}}(1,-1)\right]\,, \qquad \text{(F.40)}\\
F_2(Q^2) &:= \lim_{k\to\infty} f_2(Q^2,k) = -\frac{1}{|\,\mathrm{e}\,|\,\eta}\lim_{k\to\infty}\frac{1}{2k}J^0_{\mathrm{V}}(1,-1)\,, \qquad \text{(F.41)}
\end{aligned}$$

with $\eta = Q^2/(4m^2_{\mathrm{C}})$. For the magnetic form factor G_{M} we need the current matrix element J^2_{11}. From the expansion of the nucleon current around $k=\infty$, cf. Eq. (5.16), we see that the second component of the nucleon current is suppressed by $1/k$. By pulling the factor $1/k$ out of the integral it is seen to cancel with the factor $\sqrt{k_{\mathrm{C}}^0 k_{\mathrm{C}}'^0}$. Thus we find the following overlap integral:

$$\begin{aligned}
&\frac{1}{|\,\mathrm{e}\,|}\, J^2_{\mu_j'\mu_j}(Q^2) \\
&= \frac{1}{4\pi}\int \mathrm{d}^3\tilde{k}_1' \sqrt{\frac{m_{12}}{m_{12}'}} u_{n0}^*\left(\tilde{k}_1'\right) u_{n0}\left(\tilde{k}_1\right) \frac{m_{12}'}{(m_{12}' + 2\tilde{k}_1'^3)} \\
&\quad \times |\,\mathrm{e}\,| \left\{ \left[F_1^1(Q^2) + F_1^2(Q^2)\right] \left(\tilde{k}_1'^2 \mathcal{S}_1^{\mu_j'\mu_j} + \frac{\mathrm{i}\,Q}{2}\mathcal{S}_3^{\mu_j'\mu_j}\right)\right. \\
&\quad \left. + \sqrt{\tau}\left[F_2^1(Q^2) + F_2^2(Q^2)\right]\left(\mathrm{i}\,m\,\mathcal{S}_3^{\mu_j'\mu_j} + \tilde{k}_1'^2\mathcal{S}_2^{\mu_j'\mu_j}\right)\right\}\,, \qquad \text{(F.42)}
\end{aligned}$$

with the spin factor $\mathcal{S}_3^{\mu_j'\mu_j}$ given by Eq. (5.53). Then the magnetic form factor is extracted using Eq. (F.23) as

$$G_{\mathrm{M}}(Q^2) := \lim_{k\to\infty} g_{\mathrm{M}}(Q^2,k) = -\frac{\mathrm{i}}{|\,\mathrm{e}\,|\,Q}\, J^2_{11}(Q^2)\,. \qquad \text{(F.43)}$$

F.2 Projection Tensors

To see explicitly that the expressions (5.57)-(5.59) are identical with the integrals of Eqs. (5.48)-(5.50) we have to investigate the particular expressions that appear under the integral after contracting with the projection tensors. Using our standard kinematics we obtain the following expressions of interest in the limit $k \to \infty$:

$$\frac{\sqrt{k_{\mathrm{C}}^0 k_{\mathrm{C}}'^0}}{k_1^0} \overset{k\to\infty}{\longrightarrow} \frac{2m_{12}'}{m_{12}' + 2\tilde{k}_1'^3}\,, \qquad \text{(F.44)}$$

$$B_{\mathrm{c}}(-\boldsymbol{w}_{\mathrm{C}})q \overset{k\to\infty}{\longrightarrow} \left(\frac{Q^2}{2m_{\mathrm{C}}}, Q, 0, -\frac{Q^2}{2m_{\mathrm{C}}}\right)\,, \qquad \text{(F.45)}$$

$$B_{\mathrm{c}}(-\boldsymbol{w}_{\mathrm{C}}')q \overset{k\to\infty}{\longrightarrow} \left(-\frac{Q^2}{2m_{\mathrm{C}}}, Q, 0, \frac{Q^2}{2m_{\mathrm{C}}}\right)\,, \qquad \text{(F.46)}$$

$$B_{\mathrm{c}}(-\boldsymbol{w}_{\mathrm{C}})K_{\mathrm{C}} \overset{k\to\infty}{\longrightarrow} \left(2m_{\mathrm{C}} + \frac{Q^2}{2m_{\mathrm{C}}}, Q, 0, -\frac{Q^2}{2m_{\mathrm{C}}}\right)\,, \qquad \text{(F.47)}$$

$$B_{\mathrm{c}}(-\boldsymbol{w}_{\mathrm{C}}')K_{\mathrm{C}} \overset{k\to\infty}{\longrightarrow} \left(2m_{\mathrm{C}} + \frac{Q^2}{2m_{\mathrm{C}}}, -Q, 0, -\frac{Q^2}{2m_{\mathrm{C}}}\right)\,, \qquad \text{(F.48)}$$

$$2\frac{B_{\mathrm{c}}(-\boldsymbol{w}_{\mathrm{C}})K_{\mathrm{e}}}{(K_{\mathrm{e}}\cdot K_{\mathrm{C}})} \overset{k\to\infty}{\longrightarrow} \frac{1}{m_{\mathrm{C}}}\,(1,0,0,-1)\,, \qquad \text{(F.49)}$$

$$2\frac{B_{\mathrm{c}}(-\boldsymbol{w}_{\mathrm{C}}')K_{\mathrm{e}}}{(K_{\mathrm{e}}\cdot K_{\mathrm{C}})} \overset{k\to\infty}{\longrightarrow} \frac{1}{m_{\mathrm{C}}}\,(1,0,0,-1)\,, \qquad \text{(F.50)}$$

$$\begin{aligned}
&B_{\mathrm{c}}(-\boldsymbol{w}_{\mathrm{C}}')^{\lambda}{}_{\sigma}\, \mathrm{g}^{\sigma\tau}\, B_{\mathrm{c}}(-\boldsymbol{w}_{\mathrm{C}})^{\nu}{}_{\tau} \\
&\overset{k\to\infty}{\longrightarrow} \begin{pmatrix} 1 + Q^2/(2m_{\mathrm{C}}^2) & Q/m_{\mathrm{C}} & 0 & -Q^2/(2m_{\mathrm{C}}^2) \\ -Q/m_{\mathrm{C}} & -1 & 0 & Q/m_{\mathrm{C}} \\ 0 & 0 & -1 & 0 \\ -Q^2/(2m_{\mathrm{C}}^2) & -Q/m_{\mathrm{C}} & 0 & -1 + Q^2/(2m_{\mathrm{C}}^2) \end{pmatrix}^{\lambda\nu}\,. \qquad \text{(F.51)}
\end{aligned}$$

Furthermore, the expressions involving the constituent currents

$$\begin{aligned} B_{\mathrm{c}}(-\boldsymbol{w}_{\mathrm{C}}^{(\prime)})^{\mu}{}_{\tau} J_i^{\tau}\left(\boldsymbol{k}_i', \mu_i'; \boldsymbol{k}_i, \mu_i\right)\,, \quad & q_{\tau} J_i^{\tau}\left(\boldsymbol{k}_i', \mu_i'; \boldsymbol{k}_i, \mu_i\right)\,, \\ K_{\mathrm{e}\tau} J_i^{\tau}\left(\boldsymbol{k}_i', \mu_i'; \boldsymbol{k}_i, \mu_i\right)/(K_{\mathrm{e}} \cdot K_{\mathrm{C}}) \quad \text{and} \quad & K_{\mathrm{C}\tau} J_i^{\tau}\left(\boldsymbol{k}_i', \mu_i'; \boldsymbol{k}_i, \mu_i\right) \end{aligned} \tag{F.52}$$

are seen to be finite in the limit $k \to \infty$. They are rather lengthy and will not be given here explicitly. Also, the spin matrix

$$\begin{aligned} & D^{\frac{1}{2}}_{\mu_1 \tilde{\mu}_1}\left[\underline{R}_{\mathrm{W_c}}\left(\tilde{w}_1, B_{\mathrm{c}}(\boldsymbol{w}_{12})\right)\right] (\sigma_\nu)_{\tilde{\mu}_1 \tilde{\mu}_2} D^{\frac{1}{2}}_{\tilde{\mu}_2 \tilde{\mu}_2'}\left[\underline{R}_{\mathrm{W_c}}\left(\tilde{w}_2', B_{\mathrm{c}}^{-1}(\boldsymbol{w}_{12}) B_{\mathrm{c}}(\boldsymbol{w}_{12}')\right)\right] \\ & \quad \times (\sigma_\lambda)_{\tilde{\mu}_2' \tilde{\mu}_1'} D^{\frac{1}{2}}_{\tilde{\mu}_1' \mu_1'}\left[\underline{R}^{-1}_{\mathrm{W_c}}\left(\tilde{w}_1', B_{\mathrm{c}}(\boldsymbol{w}_{12}')\right)\right] \end{aligned} \tag{F.53}$$

is a lengthy but also finite in the limit $k \to \infty$. Therefore, the form factors defined in Eqs. (5.57)-(5.59) are finite in the limit $k \to \infty$. Putting everything together it can be shown that Eqs. (5.57)-(5.59) are actually equivalent with the integrals given in Eqs. (5.48)-(5.50).[1]

---

[1] Due to the complexity of the problem we have carried out the proof using the symbolic MATHEMATICA© programming language.

Appendix G

Meson-Exchange Potentials in the Static Limit

Here we use appropriately normalized Dirac spinors given by

$$\tilde{u}_\sigma(\boldsymbol{p}) = \frac{1}{\sqrt{2m}}\, u_\sigma(\boldsymbol{p})\,. \tag{G.1}$$

In the static approximation and taking the limit $m \to \infty$ the Dirac spinor takes the form

$$\tilde{u}_\sigma(\boldsymbol{p}) \to u^{\mathrm{nr}}_\sigma = \begin{pmatrix} \varsigma_\sigma \\ 0 \end{pmatrix}\,, \tag{G.2}$$

with

$$\bar{u}^{\mathrm{nr}}_{\sigma'}\, u^{\mathrm{nr}}_\sigma = \varsigma^\dagger_{\sigma'}\, \varsigma_\sigma = \delta_{\sigma'\sigma}\,. \tag{G.3}$$

Then is easy to see that the second-order amplitude for the scalar meson exchange $m^{\mathrm{N}\sigma}_{\mathrm{int}}$ in Eq. (6.10) becomes just the static potential in Eq. (6.11):

$$g_\sigma^2\, \bar{u}^{\mathrm{nr}}_{\tilde{\mu}'_1}\, u^{\mathrm{nr}}_{\tilde{\mu}_1}\, \frac{1}{-(\tilde{\boldsymbol{k}}'_1 - \tilde{\boldsymbol{k}}_1)^2 - m_\sigma^2}\, \bar{u}^{\mathrm{nr}}_{\tilde{\mu}'_2}\, u^{\mathrm{nr}}_{\tilde{\mu}_2} = -g_\sigma^2 \frac{\delta_{\tilde{\mu}'_1\tilde{\mu}_1}\delta_{\tilde{\mu}'_2\tilde{\mu}_2}}{\tilde{\boldsymbol{q}}_1^2 + m_\sigma^2}\,, \tag{G.4}$$

where $\tilde{\boldsymbol{q}}_1 = \tilde{\boldsymbol{k}}'_1 - \tilde{\boldsymbol{k}}_1$ is the three-momentum transfer. For the vector meson exchange contribution $m^{\mathrm{N}\omega}_{\mathrm{int}}$ in Eq. (6.10) we first concentrate on the contributions of the second term of the ω-meson propagator which reads

$$-\, g_\omega^2 \bar{\tilde{u}}_{\tilde{\mu}'_1}(\tilde{\boldsymbol{k}}'_1)\gamma_\mu \tilde{u}_{\tilde{\mu}_1}(\tilde{\boldsymbol{k}}_1) \frac{(\tilde{k}'^\mu_1 - \tilde{k}^\mu_1)(\tilde{k}'^\nu_2 - \tilde{k}^\nu_2)/m_\omega^2}{(\tilde{k}'_1 - \tilde{k}_1)^2 - m_\omega^2} \bar{\tilde{u}}_{\tilde{\mu}'_2}(\tilde{\boldsymbol{k}}'_2)\gamma_\nu \tilde{u}_{\tilde{\mu}_2}(\tilde{\boldsymbol{k}}_2). \tag{G.5}$$

Making use of the Dirac equations for the spinors, Eqs. (3.55) and (3.56), we have

$$\bar{\tilde{u}}_{\tilde{\mu}'_1}(\tilde{\boldsymbol{k}}'_1)\gamma_\mu(\tilde{k}'^\mu_1 - \tilde{k}^\mu_1)\tilde{u}_{\tilde{\mu}_1}(\tilde{\boldsymbol{k}}_1) = \bar{\tilde{u}}_{\tilde{\mu}'_1}(\tilde{\boldsymbol{k}}'_1)(m_{\mathrm{N}} - m_{\mathrm{N}})\tilde{u}_{\tilde{\mu}_1}(\tilde{\boldsymbol{k}}_1) = 0\,. \tag{G.6}$$

Thus, we find that the second term of $m^{\mathrm{N}\omega}_{\mathrm{int}}$ vanishes for on-shell nucleons. For the contributions of the first term of the ω-meson propagator

$$-\, g_\omega^2 \bar{\tilde{u}}_{\tilde{\mu}'_1}(\tilde{\boldsymbol{k}}'_1)\gamma_\mu \tilde{u}_{\tilde{\mu}_1}(\tilde{\boldsymbol{k}}_1) \frac{\mathrm{g}^{\mu\nu}}{(\tilde{k}'_1 - \tilde{k}_1)^2 - m_\omega^2} \bar{\tilde{u}}_{\tilde{\mu}'_2}(\tilde{\boldsymbol{k}}'_2)\gamma_\nu \tilde{u}_{\tilde{\mu}_2}(\tilde{\boldsymbol{k}}_2) \tag{G.7}$$

we use the standard representation of the γ-matrices, cf. Eq. (B.1). In the static limit the spatial components of the nucleon current, being proportional to the three-momentum divided by the mass, vanish:

$$\bar{\tilde{u}}_{\tilde{\mu}_1'}(\tilde{\boldsymbol{k}}_1')\gamma^i\tilde{u}_{\tilde{\mu}_1}(\tilde{\boldsymbol{k}}_1) \approx \bar{u}^{\mathrm{nr}}_{\tilde{\mu}_1'}\gamma^i u^{\mathrm{nr}}_{\tilde{\mu}_1} = 0, \quad \forall\, i = 1, \ldots, 3\,. \tag{G.8}$$

Thus the three-vector part of the contraction of the currents vanishes:

$$-\, g_\omega^2\, \bar{u}^{\mathrm{nr}}_{\tilde{\mu}_1'}\gamma^i u^{\mathrm{nr}}_{\tilde{\mu}_1}\, \frac{1}{\tilde{\boldsymbol{q}}_1^2 + m_\omega^2}\, \bar{u}^{\mathrm{nr}}_{\tilde{\mu}_2'}\gamma^i u^{\mathrm{nr}}_{\tilde{\mu}_2} = 0\,. \tag{G.9}$$

We are left only with the temporal components $\bar{\tilde{u}}_{\tilde{\mu}_1'}(\tilde{\boldsymbol{k}}_1')\gamma^0\tilde{u}_{\tilde{\mu}_1}(\tilde{\boldsymbol{k}}_1)$ which become unity in the non-relativistic limit:

$$\bar{\tilde{u}}_{\tilde{\mu}_1'}(\tilde{\boldsymbol{k}}_1')\gamma^0\tilde{u}_{\tilde{\mu}_1}(\tilde{\boldsymbol{k}}_1) \approx \bar{u}^{\mathrm{nr}}_{\tilde{\mu}_1'}\gamma^0 u^{\mathrm{nr}}_{\tilde{\mu}_1} = \delta_{\tilde{\mu}_1'\tilde{\mu}_1}\,. \tag{G.10}$$

Therefore, the second-order contribution in the static limit is

$$-\, g_\omega^2\bar{u}^{\mathrm{nr}}_{\tilde{\mu}_1'}\gamma^0 u^{\mathrm{nr}}_{\tilde{\mu}_1}\, \frac{1}{-\boldsymbol{q}^2 - m_\omega^2}\bar{u}^{\mathrm{nr}}_{\tilde{\mu}_2'}\gamma^0 u^{\mathrm{nr}}_{\tilde{\mu}_2} = g_\omega^2\, \frac{\delta_{\tilde{\mu}_1'\tilde{\mu}_1}\delta_{\tilde{\mu}_2'\tilde{\mu}_2}}{\boldsymbol{q}^2 + m_\omega^2}\,, \tag{G.11}$$

which is just the static potential given in Eq. (6.12).

p_i^μ Four-momentum operator of particle i

$\hat{P}^\mu$ Total four-momentum operator

$\hat{P}^\mu_n$ Four-momentum operator of the free n-particle system

$|\mathit{\Psi}\rangle$ State vector

$\tilde{\mathit{\Psi}}_{00}(\boldsymbol{r})$ Deuteron wave function in coordinate space

$\mathit{\Psi}_{nj\mu_j\mu_1\mu_2}(\tilde{\boldsymbol{k}})$ 2-particle wave function

$\hat{\psi}(x)$ Local spin-1/2 fermion field operator

$q^\mu_{(\mathrm{N})}$ Four-momentum transfer (on the nucleon) in the overall center-of-momentum system

$Q^2_{(\mathrm{N})}$ Four-momentum transfer squared (on the nucleon)

$Q_{\mathrm{q/e}}$ Quark/electron charge

$Q_{\rho/\mathrm{D}}$ Electric quadrupole moment of the ρ-meson/deuteron

$\boldsymbol{r}$ Position three-vector

$\boldsymbol{\rho}$ Rapidity

$R_{\mathrm{W_c}}$ Wigner rotation associated with canonical boosts

$R_{\mathrm{W_g}}$ Wigner rotation associated with general boosts

$R_{\mathrm{W_h}}$ Wigner rotation associated with helicity boosts

s Mandelstam variable

s Quantum number of total spin of the cluster

$\mathcal{S}$ Spin rotation factor for spin-0 bound states

$\hat{\boldsymbol{s}}$ Total spin operator of the cluster

$\boldsymbol{\sigma}$ Vector of Pauli matrices

σ_0 (2×2)-unit matrix

σ_i Spin projection of particle i

σ_j 3-projection of $\hat{\boldsymbol{j}}_{\mathrm{c}}$

$\hat{\sigma}_{\mathrm{PV}}(x)$ σ Pauli-Villars field operator

ς_σ Pauli spinor

$\hat{\sigma}(x)$ σ meson field operator

$\mathcal{S}_i^{\mu_j'\mu_j}$ Spin rotation factors for spin-1 bound states

$S(\underline{\Lambda})$ Four-spinor representation of the $\mathrm{SL}(2,\mathbb{C})$

$\mathcal{S}_{\mu_1\mu_1'}^{\mu_j'\mu_j}$ Short-hand notation for 3 Wigner D-functions and 2 spin-1 Clebsch-Gordan coefficients

t Mandelstam variable

$T_{20}(Q^2)$ Tensor polarization

$T(a)$ Space-time translation

τ Proper time

$\boldsymbol{\theta}$ Rotation parameter

$\theta(x)$ Heavyside step function

$\hat{T}_i(\underline{a})$ Space-time translation operator for particle i

$\hat{\mathcal{T}}_{\mathrm{int}}^{\mu\nu}(x)$ Interaction energy-momentum tensor operator

$u_0(\tilde{k})$ Radial S-wave function of the deuteron in momentum space

$\tilde{u}_0(r)$ Radial S-wave function of the deuteron in configuration space

$\hat{U}_{12\cdots n}(\underline{\mathit{\Lambda}}, \underline{a})$ Unitary representation of the $\mathrm{ISL}(2,\mathbb{C})$ acting on n-particle tensor-product states

$\hat{U}_i(\underline{\mathit{\Lambda}}, \underline{a})$ Unitary irreducible representation of the $\mathrm{ISL}(2,\mathbb{C})$

$\hat{U}(\underline{\mathit{\Lambda}}, \underline{a})$ Unitary representation of the $\mathrm{ISL}(2,\mathbb{C})$

$u_{n0}(\tilde{k})$ Radial S-wave function

$u_{nl}(\tilde{k})$ Radial wave function of harmonic oscillator

$u^j_{nls}(\tilde{k})$ Radial wave function

$u_\sigma(\boldsymbol{p})$ Dirac spinor for spin-1/2 fermions

$\tilde{u}_\sigma(\boldsymbol{p})$ Dirac spinor for spin-1/2 fermions normalized to unity

u^{nr}_σ Dirac spinor for spin-1/2 fermions in the static approximation

V^μ Four-velocity of the free overall system

v^μ_{12} Four-velocity of the free cluster

v^μ_i Four-velocity of particle i

$|V; \boldsymbol{k}_1, \mu_1; \boldsymbol{k}_2, \mu_2; \ldots; \boldsymbol{k}_n, \mu_n\rangle$ n-particle velocity state

$|V; \{\boldsymbol{k}_i, \mu_i\}\rangle$ Short-hand notation for n-particle velocity state

$\hat{V}^{(\mathrm{C})}_{\mathrm{opt}}(M)$ One-photon-exchange optical potential (on the bound-state level)

$V(r)$ Meson-exchange potential in configuration space

$v_\sigma(\boldsymbol{p})$ Dirac spinor for spin-1/2 anti-fermions

$w_0(r)$ Reduced S-wave function of the deuteron

w^μ_{12} Four-velocity of the free cluster in the overall center-of-momentum system

w^μ_i Four-velocity of particle i in the overall center-of-momentum system

$\tilde{w}^\mu_i$ Four-velocity of constituent i in the cluster center-of-momentum system

$\hat{x}_{\mathrm{c}}$ Newton-Wigner position operator of the cluster

$\hat{X}_{\mathrm{c}}$ Newton-Wigner position operator

x^μ Minkowski-space position four-vector

$Y_{l\mu_l}(\hat{\tilde{\boldsymbol{k}}})$ Spherical harmonic functions

z Longitudinal momentum fraction

Acknowledgements

First of all, I would like to thank my supervisor Wolfgang Schweiger. He guided and supported me throughout my studies in many different ways. His thorough and careful approach to physics formed my ideas and it was always a great pleasure to work with him. I am also very grateful for the opportunity of participating at the doctoral program 'Hadrons in Vacuum, Nuclei and Stars'. I want to thank William H. Klink for his constructive suggestions and his helpful ideas, in particular, on the cluster problem. I would like to express my gratitude to Bernard L. G. Bakker for his supportive supervision of our joint project on the Walecka model and for being a referee of this thesis. At this point I would also like to thank the whole particle physics group at the VU University Amsterdam for their warm hospitality. I owe thanks to my mentor Willibald Plessas for his support in many ways. In particular, I would like to mention the numerous animated discussions with him which encouraged my critical thinking. I also want to thank the whole Graz group and, in particular, Thomas Melde for many discussions. I would like to thank Fritz Coester and Wayne Polyzou for the interesting and elucidating discussions and I am much obliged to the University of Iowa for their warm hospitality.

Furthermore, I will always be grateful for the love and support I have received from my parents and from my family. I would also like to mention my friends and colleagues. Thank you for always being there for me!

Finally, I thank Justine for everything.

Financial Support This thesis was financially supported by the Austrian Science Fund FWF under Grant No. DK W1203-N16 (Doctoral Program 'Hadrons in Vacuum, Nuclei and Stars'), as well as by the Province of Styria, Austria with a Ph.D. grant. The research stay at the University of Iowa in Iowa City, USA was also financially supported by a "Mobilitätszuschuss der Karl-Franzens Universität Graz" and by the University of Iowa.
